What is claimed is:

1. A cutting apparatus that cuts, along cutting lines, an object to be cut in which a plurality of separating elements are connected together by means of connecting portions, and in which the cutting lines within the separating elements that are mutually adjacent to each other are set on mutually different straight lines, comprising:

a cutting table on which the object to be cut is held by means of suction;

a cutting mechanism that, using a blade, cuts the object to be cut; and

a separating element transporting portion that, in a state in which the connecting portions have been cut by the cutting mechanism so that the separating elements have been separated from each other, transports one of the mutually adjacent separating elements away from the cutting table,

wherein the cutting table comprises a first table suctioning portion that, regarding the mutually adjacent separating elements, suctions one of the separating elements, and a second table suctioning portion that is independent of the first table suctioning portion and suctions the other one of the separating elements.

2. The cutting apparatus according to Claim 1, wherein, in a state in which the connecting portions have been cut by the cutting mechanism so that the separating elements have been separated from each other, the cutting table stops the suctioning of the separating elements by either the first table suctioning portion or the second table suctioning portion, and

the separating element transporting portion transports the separating element whose suctioning by the cutting table has been stopped away from the cutting table.

3. A cutting apparatus that cuts, along cutting lines, an object to be cut in which a plurality of separating elements are connected together by means of connecting portions,

and in which the cutting lines within the separating elements that are mutually adjacent to each other are set on mutually different straight lines, comprising:

a cutting table on which the object to be cut is held by means of suction;

a cutting mechanism that, using a blade, cuts the object to be cut; and

a separating element transporting portion that, in a state in which the connecting portions have been cut by the cutting mechanism so that the separating elements have been separated from each other, transports one of the mutually adjacent separating elements away from the cutting table,

wherein the plurality of separating elements are arranged in rows in the direction in which they will be cut by the blade, and their placement modes are divided into at least two groups, and the cutting lines of the separating elements of one group are positioned on the same straight lines, while the cutting lines of the separating elements of another group are positioned on the same straight lines, and wherein

the separating element transporting portion transports either the one group of separating elements or the other group of separating elements.

4. The cutting apparatus according to Claim 3, further comprising:

a transporting mechanism that transports the object to be cut to the cutting table; and

a discharging mechanism that discharges cut products that have been cut at the cutting table, wherein

the transporting mechanism or the discharging mechanism function as the separating elements transporting portion;,

the transporting mechanism or the discharging mechanism comprises:

a first transporting suction portion that suctions the separating elements of the one group; and

a second transporting suction portion that is independent of the first transporting suction portion and suctions the separating elements of the other group, and wherein

the transporting mechanism or the discharging mechanism functions as the separating elements transporting portion using the first transporting suction portion or the second transporting suction portion.

5. The cutting apparatus according to any one of Claim 1 through Claim 3, further comprising:

a transporting mechanism that transports the object to be cut to the cutting table; and

a discharging mechanism that discharges cut products that have been cut at the cutting table, wherein

the transporting mechanism or the discharging mechanism function as the separating elements transporting portion.

6. The cutting apparatus according to any one of Claim 1 through Claim 5, wherein the separating element transporting portion transports one of the mutually adjacent separating elements from the cutting table to another cutting table.

7. The cutting apparatus according to any one of Claim 1 through Claim 5, wherein the separating element transporting portion transports one of the mutually adjacent separating elements from the cutting table to a temporary placement table.

8. The cutting apparatus according to any one of Claim 1 through Claim 5, wherein the separating element transporting portion holds the one of the mutually adjacent separating elements after having transported it from the cutting table.

9. A method of manufacturing a cut product using the cutting apparatus according to any one of Claim 1 through Claim 8.
