

ADJUSTABLE FRACTURING HEAD AND MANIFOLD SYSTEM

BACKGROUND

[0001] This section is intended to introduce the reader to various aspects of art that may be related to various aspects of the presently described embodiments. This
5 discussion is believed to be helpful in providing the reader with background information to facilitate a better understanding of the various aspects of the present embodiments. Accordingly, it should be understood that these statements are to be read in this light, and not as admissions of prior art.

[0002] In order to meet consumer and industrial demand for natural resources,
10 companies often invest significant amounts of time and money in searching for and extracting oil, natural gas, and other subterranean resources from the earth. Particularly, once a desired subterranean resource is discovered, drilling and production systems are often employed to access and extract the resource. These systems may be located onshore or offshore depending on the location of a desired resource. Further, such
15 systems generally include a wellhead assembly through which the resource is extracted. These wellhead assemblies may include a wide variety of components, such as various casings, valves, fluid conduits, and the like, that control drilling or extraction operations.

[0003] Additionally, such wellhead assemblies may use a fracturing tree and other components to facilitate a fracturing process and enhance production from a well. As
20 will be appreciated, resources such as oil and natural gas are generally extracted from fissures or other cavities formed in various subterranean rock formations or strata. To facilitate extraction of such resources, a well may be subjected to a fracturing process that creates one or more man-made fractures in a rock formation. This facilitates, for example, coupling of pre-existing fissures and cavities, allowing oil, gas, or the like to
25 flow into the wellbore. Such fracturing processes typically include injecting a fracturing fluid—which is often a mixture including sand and water—into the well to increase the well's pressure and form the man-made fractures. A fracturing manifold may provide fracturing fluid to one or more fracturing trees via fracturing lines (e.g., pipes). But the fracturing manifolds and associated fracturing tress are typically large and heavy, and

may be mounted to other equipment at a fixed location, making adjustments between the fracturing manifold and a fracturing tree difficult.

SUMMARY

[0004] Certain aspects of some embodiments disclosed herein are set forth below.

- 5 It should be understood that these aspects are presented merely to provide the reader with a brief summary of certain forms the invention might take and that these aspects are not intended to limit the scope of the invention. Indeed, the invention may encompass a variety of aspects that may not be set forth below.

- [0005] Embodiments of the present disclosure generally relate to adjustable
10 fracturing systems that facilitate alignment and coupling of a fracturing manifold with a fracturing tree via a fluid connection. In one embodiment, a fracturing system includes one or more adjustment joints that each provide at least one degree of freedom in aligning a fluid connection with a fracturing manifold and a fracturing tree. The adjustment joints may be provided in the form of fracturing heads or in some other
15 form, such as pipe connectors. More specifically, an adjustment joint in the fracturing system may include a dimension that may be varied by a user to facilitate connection of the fracturing manifold and the fracturing tree in an efficient manner (e.g., by allowing the user to compensate for unexpected alignment issues during connection).

- [0006] Various refinements of the features noted above may exist in relation to
20 various aspects of the present embodiments. Further features may also be incorporated in these various aspects as well. These refinements and additional features may exist individually or in any combination. For instance, various features discussed below in relation to one or more of the illustrated embodiments may be incorporated into any of the above-described aspects of the present disclosure alone or in any combination.
25 Again, the brief summary presented above is intended only to familiarize the reader with certain aspects and contexts of the some embodiments without limitation to the claimed subject matter.

BRIEF DESCRIPTION OF THE DRAWINGS

[0007] These and other features, aspects, and advantages of certain embodiments will become better understood when the following detailed description is read with reference to the accompanying drawings in which like characters represent like parts
5 throughout the drawings, wherein:

[0008] FIG. 1 generally depicts an adjustable fracturing system in accordance with an embodiment of the present disclosure;

[0009] FIG. 2 is a diagram of the adjustable fracturing system of FIG. 1 with a fracturing manifold coupled to multiple fracturing trees in accordance with an
10 embodiment of the present disclosure;

[0010] FIG. 3 is a perspective view of certain components of the adjustable fracturing system, including the fracturing manifold, one fracturing tree, and several adjustment joints in accordance with an embodiment of the present disclosure;

[0011] FIG. 4 is a perspective view of an adjustment joint in the form of a
15 fracturing head in accordance with an embodiment of the present disclosure;

[0012] FIG. 5 is a cross-section of the fracturing head of FIG. 4 in accordance with an embodiment of the present disclosure;

[0013] FIG. 6 generally depicts the fracturing head of FIGS. 4 and 5 following adjustment of the fracturing head to increase its length in accordance with an
20 embodiment of the present disclosure;

[0014] FIG. 7 is a perspective view of an adjustment joint in the form of a fracturing head having inlet and outlet ports that are not axially aligned with each other in accordance with an embodiment of the present disclosure;

[0015] FIG. 8 is a partial cross-section of a fracturing head including a test port to
25 enable integrity testing between two seals of the fracturing head in accordance with an embodiment of the present disclosure; and

[0016] FIG. 9 is a cross-section of an adjustment joint in the form of a pipe connector having a length that may be varied in accordance with an embodiment of the present disclosure.

DETAILED DESCRIPTION OF SPECIFIC EMBODIMENTS

5 [0017] One or more specific embodiments of the present disclosure will be described below. In an effort to provide a concise description of these embodiments, all features of an actual implementation may not be described in the specification. It should be appreciated that in the development of any such actual implementation, as in any engineering or design project, numerous implementation-specific decisions must be
10 made to achieve the developers' specific goals, such as compliance with system-related and business-related constraints, which may vary from one implementation to another. Moreover, it should be appreciated that such a development effort might be complex and time consuming, but would nevertheless be a routine undertaking of design, fabrication, and manufacture for those of ordinary skill having the benefit of this
15 disclosure.

[0018] When introducing elements of various embodiments, the articles "a," "an," "the," and "said" are intended to mean that there are one or more of the elements. The terms "comprising," "including," and "having" are intended to be inclusive and mean that there may be additional elements other than the listed elements. Moreover, any use
20 of "top," "bottom," "above," "below," other directional terms, and variations of these terms is made for convenience, but does not require any particular orientation of the components.

[0019] Turning now to the present figures, an example of a fracturing system 10 is provided in FIGS. 1 and 2 in accordance with one embodiment. The fracturing system
25 10 facilitates extraction of natural resources (e.g., oil or natural gas) from a well 12 via a wellbore 14 and a wellhead 16. Particularly, by injecting a fracturing fluid into the well 12, the fracturing system 10 increases the number or size of fractures in a rock formation or strata to enhance recovery of natural resources present in the formation. In the presently illustrated embodiment, the well 12 is a surface well accessed by

equipment of wellhead 16 installed at surface level (i.e., on ground 18). But it will be appreciated that natural resources may be extracted from other wells, such as platform or subsea wells.

[0020] The fracturing system 10 includes various components to control flow of a fracturing fluid into the well 12. For instance, the depicted fracturing system 10 includes a fracturing tree 20 and a fracturing manifold 22. The fracturing tree 20 includes at least one valve that controls flow of the fracturing fluid into the wellhead 16 and, subsequently, into the well 12. Similarly, the fracturing manifold 22 includes at least one valve that controls flow of the fracturing fluid to the fracturing tree 20 by a conduit or fluid connection 26 (e.g., pipes).

[0021] The fracturing manifold 22 is mounted on at least one skid 24 (e.g., a platform mounted on rails) to enable movement of the fracturing manifold 22 with respect to the ground 18. As depicted in FIG. 2, the fracturing manifold 22 is connected to provide fracturing fluid to multiple fracturing trees 20 and wellheads 16. But it is noted that the fracturing manifold 22 may instead be coupled to a single fracturing tree 20 in full accordance with the present techniques. In one embodiment in which the fracturing manifold 22 is coupled to multiple fracturing trees 20, various valves of the fracturing manifold 22 may be mounted on separate skids 24 to enable variation in the spacing between the valves. And in at least some instances, as described in further detail below, such a configuration allows for easier alignment of the fluid connection 26 between the fracturing manifold 22 and the fracturing tree 20.

[0022] Fracturing fluid from a supply 28 is provided to the fracturing manifold 22. In FIG. 1, a connector 30 receives fracturing fluid from the supply 28 through a conduit or fluid connection 32 (e.g., pipes or hoses) and then transmits the fluid to the fracturing manifold 22 by way of a subterranean conduit or fluid connection 34 (e.g., pipes). In one embodiment, the fracturing fluid supply 28 is provided by one or more trucks that deliver the fracturing fluid, connect to the connector 30, and pump the fluid into the fracturing manifold 22 via the connector 30 and connections 32 and 34. In another embodiment, the fracturing fluid supply 28 is in the form of a reservoir from which fluid may be pumped into the fracturing manifold 22. But any other suitable

sources of fracturing fluid and manners for transmitting such fluid to the fracturing manifold may instead be used.

[0023] A portion 40 of the fracturing system 10 is illustrated in FIG. 3 in accordance with one embodiment. In the depicted embodiment, the portion 40 includes the fracturing tree 20 and the fracturing manifold 22, as well as several adjustment joints that enable alignment of the connection line (i.e., fluid connection 26) between the fracturing tree 20 and the fracturing manifold 22. The manifold 22 includes a conduit 42 that routes fracturing fluid to valves 44 and 46. These valves 44 and 46 are coupled to connecting blocks 48 and 50 of the conduit 42 to receive fracturing fluid from the fluid supply 28 via connections 32 and 24. The fracturing fluid may then be routed through fluid connection 26 to a respective fracturing tree 20. Although the present embodiment includes two valves 44 and two valves 46, any other suitable number of valves may instead be used to control flow of fracturing fluid to fracturing trees 20. Further, while the depicted fluid connection 26 includes a single flow path or conduit (which may be a fracturing line with a seven-inch bore in one instance) between the fracturing tree 20 and the fracturing manifold 22, a fracturing system may include a greater number of conduits between the fracturing manifold and a fracturing tree in other embodiments.

[0024] The fracturing tree 20 is provided in the form of a horizontal fracturing tree in FIG. 3, though other embodiments may include a different style of fracturing tree (e.g., a vertical tree). The depicted fracturing tree 20 includes valves 52 to control flow of fracturing fluid through a horizontal portion of the tree 20. The tree 20 also includes a master valve 54 to control flow of fluids (e.g., fracturing fluids or production fluids) to or from the attached wellhead 16 (FIG. 1), and a port 56 allowing access to the wellhead 16 through the master valve 54. In other embodiments, the valve 54 may be omitted (e.g., in a composite tree arrangement with all valves integral to one block).

[0025] The portion 40 of the fracturing system 10 also includes extendable adjustment joints that facilitate connection of the fracturing manifold 22 to the fracturing tree 20. In the presently illustrated embodiment, the adjustment joints are provided in the form of adjustable fracturing heads 60, 62, and 64 (also commonly

referred to as “goat heads”), though other forms of adjustment joints are also envisaged and may be used in accordance with the present techniques. In operation, the fracturing tree 20 may be mounted at a fixed location (i.e., coupled to the wellhead 16). The fluid connection 26 is aligned and coupled between the fracturing tree 20 and the fracturing manifold 22. The adjustment joints (e.g., the fracturing heads 60, 62, and 64 in FIG. 3) facilitate such alignment and coupling of the fluid connection by allowing an operator to manipulate the position of the fluid connection 26 by changing a dimension (e.g., length or height) of the adjustment joint. By providing three adjustment joints, each with a different axis of movement (i.e., up-and-down, forward-and-backward, and left-and-right), adjustments can be made to help facilitate coupling of the fracturing manifold 22 to the fracturing tree 20.

[0026] For example, the conduit 42 includes a fracturing head 60 that may be extended or retracted (as represented by arrow 68) to vary the length of the conduit 42 and the distance between the valves 44 and 46 (which may be mounted on separate skids 24, as discussed above, to allow relative motion between the valves 44 and 46). Such variation also provides a first degree of freedom in aligning the fluid connection 26 between the fracturing tree 20 and the fracturing manifold 22. In other words, the adjustment joint in conduit 42 allows the distance between the seal points of the fluid connection 26 at the fracturing tree 20 and at the fracturing manifold 22 to be varied in a first dimension.

[0027] Likewise, the fluid connection 26 in FIG. 3 includes the fracturing head 62 to vary the length of the fluid connection 26 in a second dimension, as represented by arrow 70. The adjustability of the fracturing head 62 provides a second degree of freedom in aligning the connection between the fracturing tree 20 and the fracturing manifold 22. Further, the portion 40 includes the fracturing head 64 having a variable length in a third dimension (as represented by arrow 72), thus providing a third degree of freedom in aligning the fluid connection 26 between the fracturing tree 20 and the fracturing manifold 22. These three degrees of freedom are provided by three adjustment joints having different directions of adjustment that are not parallel, and in some embodiments (such as in FIG. 3) the directions of adjustment are orthogonal to one another. In addition to these three translational degrees of freedom, one or more

of the adjustment joints (e.g., fracturing heads 60, 62, and 64) may also be rotated about their axes, as indicated by arrows 69, 71, and 73, to provide rotational degrees of freedom. For example, the presently depicted embodiment provides six degrees of freedom (three translational and three rotational).

5 **[0028]** While large fracturing lines (e.g., with a seven-inch bore) are traditionally difficult to adjust between a fracturing manifold and a fracturing tree, the adjustability provided in the presently disclosed system 10 enables large fracturing lines to be aligned and connected to such components more efficiently. Consequently, as depicted in FIG. 3, a single fluid connection 26 may be provided in the form of a large-bore fracturing
10 line, rather than using multiple smaller-bore fracturing lines between the fracturing manifold and a given fracturing tree.

[0029] While the presently depicted embodiment includes three adjustment joints, it is noted that other embodiments may include fewer adjustment joints providing fewer degrees of freedom in aligning the fluid connection 26. For instance, a single
15 adjustment joint may be provided to give one translational degree of freedom (e.g., up-and-down, forward-and-backward, or left-and-right) in aligning the fracturing tree 20 and the fracturing manifold 22 for the fluid connection 26. Or two adjustment joints may be provided to give two translational degrees of freedom. Such adjustment joints may also provide rotational degrees of freedom as noted above. Further still, multiple
20 adjustment joints may be aligned coaxially to provide adjustability at different locations within the system 10 (e.g., the manifold 22 may include multiple, coaxial adjustment joints).

[0030] For clarity, only a single fluid connection 26 and a single fracturing tree 20 (both of which receive fracturing fluid from the valves 44) are depicted in FIG. 3 as
25 part of portion 40 of the fracturing system 10. But it will be appreciated that the fracturing system 10 may include additional fluid connections 26 and fracturing trees 20 (see, e.g., FIG. 2). For example, valves 46 may be coupled (e.g., via outlet 74) to another fluid connection 26 leading to a different fracturing tree 20 on another wellhead 16. Further, the conduit 42 may extend beyond the depicted connection blocks 48 and 50
30 to route fracturing fluid to additional valves and associated fracturing trees 20. And the

conduit 42 may include additional adjustment joints to enable movement of such additional valves relative to another portion of the manifold 22, thereby facilitating alignment of these valves with their associated fracturing trees 20.

[0031] The fracturing head 60, in accordance with one embodiment, is illustrated in greater detail in FIGS. 4–6. In the depicted embodiment, the fracturing head 60 includes a body having a first portion 82 and a second portion 84. The body portions 82 and 84 are configured to move with respect to one another to vary a dimension of the fracturing head and facilitate connection of the fracturing manifold 22 and the fracturing tree 20 as described above. The fracturing head 60 includes fluid ports 86 and 114 (FIG. 5) to transmit fluid through the fracturing head 60. In some embodiments, such as when installed in the fracturing system 10 in the manner depicted in FIG. 3, the fluid port 86 may be considered an output port and the fluid port 114 may be considered an inlet port. In addition to the fluid port 86, the second body portion 84 includes a set of studs 88 and nuts 90 for connecting the fracturing head 60 to another component (e.g., via an API flange or other connector). Similarly, the first body portion 82 includes through holes 92 arranged in a flange 93 about the fluid port 114 for coupling to another component (e.g., also coupled to an API flange via additional studs and nuts or to another connector). The first body portion 82 includes an additional set of through holes 95 positioned radially outward from the through holes 92. The through holes 95 are aligned with mating holes 97 in a flange 99 of the second body portion 84, and the first and second body portions 82 and 84 are secured to one another with studs 94 (through the holes 95 and 97) and nuts 96.

[0032] As depicted in FIGS. 5 and 6, a bore 98 extends through the fracturing head 60 between the fluid ports 86 and 114. The bore 98 may have a diameter similar or identical to that of the components coupled to the fluid ports 86 and 114, such as seven inches in one embodiment (though other diameters may be used for the bore 98, as well as for other components). The bore may also be sized to match the inner diameter of the production casing in the well (i.e., a full bore arrangement) to facilitate the passage of tools, plugs, or the like through the fracturing head 60. The fracturing head 60 includes an adjustment collar 100 that may be rotated on threads 104 by a user to translate the collar 100 with respect to the body portion 82 or 84 of the fracturing

head 60 on which the collar is threaded (i.e., first body portion 82 in FIGS. 5 and 6). Movement of the adjustment collar 100 allows adjustment of the length of the fracturing head 60 and the distance between fluid ports 86 and 114. Particularly, as illustrated in FIG. 6, nuts 96 may be loosened on the studs 94 and the adjustable collar 100 may be moved along the first body portion 82 to lengthen the fracturing head 60. In this manner, the length (or what may instead be considered the height) of the fracturing head 60 may be varied to aid in aligning and coupling the fracturing manifold 22 and the fracturing tree 20 via the fluid connection 26, as discussed above. The fracturing head 60, as well as other adjustment joints in the system 10 (e.g., the fracturing heads 62 or 64, or the pipe connectors 130, 170, or 224 described below), may be constructed to allow for any desired amount of variation in dimension. For instance, the adjustment joints may be constructed to allow dimensional variation (e.g., lengthening) of seven inches in one embodiment, of twelve inches in another embodiment, and of eighteen inches in still another embodiment.

15 [0033] The fracturing head 60 also includes various sealing elements to inhibit fluid leakage. For instance, as depicted, fracturing head 60 includes sealing elements 102, 106, 108, 110, and 112. The sealing elements are formed of any suitable material, such as an elastomer or metal. In one embodiment, the seals 110 include CANH™ seals available from Cameron International Corporation of Houston, Texas. Also, in one embodiment movement of the collar 100 pre-loads or energizes one or more of the seals of the fracturing head 60.

25 [0034] As depicted in FIG. 7, the fracturing head 64 is generally similar to the fracturing head 60 (and the fracturing head 62, which is identical to the fracturing head 60 in one embodiment) but includes a fluid port 86 on a side face of the body portion 84 rather than on the top face. As illustrated in FIG. 3, such an arrangement enables the fracturing head 64 to connect a pipe of fluid connection 26 with the fracturing tree 20 via a bore bent at an angle (e.g., at a right angle) to change the direction of fluid flowing through the fracturing head 64. And a dimension of the fracturing head 64 may be varied in the same manner as described above with respect to fracturing head 60, thereby facilitating alignment and coupling of the fracturing tree 20 and the fracturing manifold 22 with the fluid connection 26.

[0035] In one embodiment illustrated in FIG. 8, a fracturing head (e.g., fracturing head 60, 62, or 64) includes seals 118 and 120 (rather than sealing elements 106, 108, and 110) disposed in an annular space 122. The seals 118 and 120 are formed of any suitable material, and may include metal CANH™ seals in one embodiment. The annular space 122 is bound by the body portion 82, the body portion 84, and the adjustable collar 100. A test port 124 extends from the annular space 122 (e.g., at a location between the seals 118 and 120) to an exterior surface of the body portion 84 to allow connection of a pressure monitoring device to enable monitoring or testing of the integrity of the seals 118 and 120.

[0036] While the adjustment joints of the fracturing system 10 have been described above in the form as fracturing heads, other embodiments may use other adjustment joints in addition to, or in place of, the fracturing heads. For example, one or more of the fracturing heads 60, 62, and 64 of FIG. 3 may be replaced by other adjustment joints in additional embodiments. One example of another adjustment joint is depicted in FIG. 9 in the form of a pipe connector 130. The connector 130 includes a first tubular member 132 and a second tubular member 134. The tubular members 132 and 134 may be pipes (e.g., of the fluid connection 26 or conduit 42), or they may be coupled to pipes or other conduits in any suitable fashion. The opposite ends of the connector include an inlet and an outlet, allowing fracturing fluid to flow through the connector 130 via the bores of either the members 132 and 134 themselves or of the pipes or other conduits joined by the connector 130.

[0037] The connector 130 is configured to enable relative movement between the tubular members 132 and 134 to allow variation in the length of the connector 130. Like the fracturing heads 60, 62, and 64, the connector 130 may be constructed to allow any desired range of variation in length, such as a range of seven inches or twelve inches. Various seals 136, 138, and 140 are provided between the tubular members 132 and 134. In one embodiment, the seal 136 is an elastomeric seal and the seals 138 and 140 are metal CANH™ seals.

[0038] The connector 130 also includes a collar 142 (which may also be referred to herein as union nut 142) that cooperates with a flanged collar 154 to adjust the length

of the connector 130. The union nut 142 may be coupled to the first tubular member 132 in any suitable manner. In the depicted embodiment, threads 146 allow the union nut 142 to be threaded onto the tubular member 132. The union nut 142 includes an end 150 that engages the collar 154 via threads 152, and rotation of the union nut 142 causes the collar 154 to move along the axis of the connector 130 with respect to the tubular member 132. A flange 156 of the collar 154 is coupled to a mating flange 158 of the tubular member 134 by studs 160 and nuts 162. Consequently, rotation of the union nut 142 also causes the second tubular member 134 to be moved with respect to the first tubular member 132, thereby enabling the connector 130 to be lengthened or shortened through such operation. The connector 130 may also include a test port 164 to enable monitoring of the integrity of seals 138 and 140 in a manner similar to that described above with respect to test port 124 (FIG. 8).

[0039] While the aspects of the present disclosure may be susceptible to various modifications and alternative forms, specific embodiments have been shown by way of example in the drawings and have been described in detail herein. But it should be understood that the invention is not intended to be limited to the particular forms disclosed. Rather, the invention is to cover all modifications, equivalents, and alternatives falling within the spirit and scope of the invention as defined by the following appended claims.

CLAIMS

1. A system (10) comprising:

a fracturing head (60, 62, 64) including a body having an inlet port (114), an outlet port (86), and a bore (98) to enable a fracturing fluid to flow between the inlet port and the outlet port, wherein the body is an adjustable body that permits movement of a first portion (82) of the body having the inlet port with respect to a second portion (84) of the body having the outlet port to enable variation in a dimension of the adjustable body.

2. The system of claim 1, comprising:

a fracturing manifold (22); and

a fracturing tree (20) coupled to the fracturing manifold;

wherein the fracturing head facilitates connection of the fracturing manifold to the fracturing tree through variation in the dimension of the adjustable body.

3. The system of claim 2, comprising at least one additional fracturing head (60, 62, 64) with an adjustable body that enables variation in a dimension of the additional fracturing head to facilitate connection of the fracturing manifold to the fracturing tree.

4. The system of claim 3, wherein the at least one additional fracturing head includes two additional fracturing heads (60, 62, 64) with adjustable bodies, and the fracturing head and the two additional fracturing heads provide three translational degrees of freedom (68, 70, 72) in aligning and connecting the fracturing manifold to the fracturing tree.

5. The system of claim 4, wherein the fracturing head and the two additional fracturing heads also provide three rotational degrees of freedom (69, 71, 73) in aligning and connecting the fracturing manifold to the fracturing tree.

6. The system of claim 2, comprising a single flow path between the fracturing manifold and the fracturing tree.
7. The system of claim 2, wherein the fracturing manifold is mounted on a skid (24) to enable movement of the fracturing manifold with respect to a wellhead (16).
8. The system of claim 2, comprising a plurality of fracturing trees (20) coupled to the fracturing manifold.
9. The system of claim 1, wherein the fracturing head is a single-bore fracturing head with a single inlet port and a single outlet port.
10. The fracturing head of claim 1, comprising an adjustment collar (100) threaded onto the first portion or the second portion.
11. The fracturing head of claim 10, wherein the adjustment collar allows an operator to rotate the adjustment collar to vary the dimension of the adjustable body and to energize at least one seal (106, 108, 110, 118, 120) between the first portion and the second portion.
12. The fracturing head of claim 1, wherein the first portion of the fracturing head includes a flange (93) comprising:
 - a first plurality of through holes (95) aligned with mating through holes (97) in a flange (99) of the second portion of the fracturing head; and
 - a second plurality of through holes (92) radially inward from the first plurality of through holes, wherein the second plurality of through holes enables the first portion of the fracturing head to be coupled to a fracturing manifold via a connecting flange.

13. The fracturing head of claim 1, comprising a first seal (118) and a second seal (120) disposed in an annular space (122) between the first portion and the second portion, and a test port (124) that extends from an exterior surface of the fracturing head to the annular space at a position between the first seal and the second seal.

14. A method comprising:

providing a fracturing head (60, 62, 64) having an inlet port (114) and an outlet port (86); and

installing the fracturing head in a fracturing system (10), wherein installing the fracturing head includes adjusting the height of the fracturing head to vary the distance between an inlet port and an outlet port of the fracturing head.

15. The method of claim 14, comprising testing integrity of one or more seals (118, 120) of the fracturing head via a test port (124) in the fracturing head.
