

A MUTANT HUMAN HEPATITIS B
VIRAL STRAIN AND USES THEREOF

Throughout this application, various references are referred
5 to within parentheses. Disclosures of these publications in
their entireties are hereby incorporated by reference into
this application to more fully describe the state of the art
to which this invention pertains.

10 **BACKGROUND OF THE INVENTION**

The present invention concerns the human hepatitis B virus
genome, isolated from hepatocellular carcinoma (HCC), and with
a mutation at amino acid residue 133 (Methionine to Threonine)
15 within the major surface antigen, its nucleotide sequence, the
deduced amino acid sequence of the four major proteins,
antigen, antibody, detection systems, development of effective
vaccines, and antiviral agents.

20 HCC is one of the most common human liver cancers,
particularly in Asia where 70% of the worldwide new cases are
found every year. It usually arises in cirrhotic livers as a
complication of chronic liver disease. The clinical
manifestations of HCC patients are unspecific with signs and
25 symptoms only appearing in the later stages of the cancer.

One of the major causes of chronic liver diseases is hepatitis
B viral infection. First discovered in 1963 as a human virus
that is transmitted parenterally, chronic hepatitis B viral
30 infection has been most commonly implicated in serological
undefined pathogenesis of HCC. Despite the fact that
hepatitis B virus does not display features of a complete
viral oncogene, its involvement in the development of HCC can
be attributed to various aspects of its interaction with host
35 hepatocyte cells. These include the promiscuous
transcriptional activity of the smallest viral protein, X,
which enhances the expression level of many cellular target
genes including proto-oncogenes. On the other hand,
integrated viral DNA in the host chromosomes is regularly
40 found in HCC patients. There is also evidence for an active

role in the development of HCC by the major surface antigen. This protein has served as the main detection marker for carriers of hepatitis B virus. The most antigenic epitope is a highly conserved region spanning 23 amino acid residues and located from amino acid position 124 to 147 of the major surface antigen. This small region designated as the group specific determinant "a" is found in all subtypes and isolates of hepatitis B viral genomes. Its antigenic properties seem due to its proposed double loop structure, to which the vaccine-induced neutralizing antibody binds.

Our epidemiological data indicate that the wild type major surface antigen has been found in most HCC patients. Furthermore, observation indicates that several variants of the major surface antigen from HCC patients may be involved in the pathogenesis of HCC. Direct sequencing analysis indicated that 24 out of 63 HCC patients (around 38%) carry various mutations in the "a" epitope of the major surface antigen. When both the wild type and variant cases are combined, the proportion of the variant virus carrying a mutation at amino acid residue 133, located in the first loop of the "a" epitope of the major surface antigen (Methionine to Threonine), is as high as 12.7% in 63 HCC patients from the Southeast Asia region, and present in 5 local HCC cases. However, the same mutation is found in only 2% of hepatitis B virus carriers in a random population (more than 100 cases). The significance of this variant at amino acid residue 133 is further strengthened by the fact that the proportion of variant virus at amino acid residue 145 (Glycine to Arginine), better known as a vaccine-induced mutant and located in the second loop of the "a" epitope, remains constant at 8% in hepatitis B virus carriers in the random population sample.

Although this variant hepatitis B viral strain, carrying a mutation at amino acid residue 133 (Methionine to Threonine) of the major surface antigen in HCC patients, may arise differently from those induced following vaccination (i.e. with a mutation at amino acid residue 145 of the major surface

antigen), this strain shares similar characteristics in that both are stable and cases of vertical transmission of these strains have been reported, despite effective hepatitis B virus prophylaxis and hepatitis B immunoglobulin (HBIG) being used.

The emergence of the variant human hepatitis B virus, carrying mutations in the "a" epitope of the major surface antigen, in HCC is of concern. The high proportion of the mutant virus with a substitution at amino acid residue 133 of the major surface antigen is of particular interest as it may point to a close association with the pathogenesis of HCC. This correlation would therefore require the urgent development of specific detection systems as well as effective prophylactic and therapeutic vaccines and antiviral agents. Determination of the nucleotide sequence of this mutant virus constitutes the first step towards these aims and will certainly be helpful for developing the above-mentioned diagnostic and treatment schemes.

20

SUMMARY OF THE INVENTION

This invention provides an isolated strain of Hepatitis B virus designated Human Hepatitis B Virus Surface Antigen-'S'-
5 133 Oon Strain (Methionine to Threonine) which constituent viral genome is deposited under Accession Nos. P97121501, P97121502 and P97121503 with the European Collection of Cell Culture on 15th December 1997.

10 This invention further provides an isolated nucleic acid encoding a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in
15 that the amino acid at position number 133 of such polypeptide is a threonine rather than a methionine.

This invention further provides a method of producing the polypeptide and a method of obtaining the polypeptide in
20 purified form so as to recover a purified polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino
25 acid at position number 133 of such polypeptide is a threonine rather than a methionine.

This invention further provides an oligonucleotide of at least 15 nucleotides capable of specifically hybridizing with
30 sequences of only the mutant viral strain of hepatitis B virus.

This invention further provides a method of obtaining antibodies to the polypeptide and to the antibodies produced.
35

This invention also provides use of the above-identified nucleic acid, polypeptide, peptide or antibody for determining whether a subject is infected with the above-identified viral

strain.

This invention also provides use of the above-identified nucleic acid, polypeptide, peptide or antibody for determining whether a subject has a predisposition for hepatocellular carcinoma.

This invention also provides a vaccine for preventing and treating hepatocellular carcinoma, as well as, a vaccine for treating or preventing infection by the above-identified mutant strain of hepatitis B virus.

This invention also provides a method for identifying a chemical compound which is capable of treating or preventing hepatocellular carcinoma and compositions containing such compounds.

This invention also provides a method for identifying a chemical compound which is capable of treating or preventing infection by the above-identified mutant strain and compositions containing such compounds.

BRIEF DESCRIPTION OF THE FIGURES

- Figure 1. Structure of the four open reading frames of human hepatitis B viral genome isolated from HCC (with a Methionine to Threonine mutation at amino acid residue 133 of the major surface antigen, as labeled by an asterisk). The major viral proteins: DNA polymerase, large/middle/major surface antigen, precore, core and transactivating X are denoted as P, PreS 1/PreS2/S, PreC, C and X respectively.
- Figure 2. Strategy of cloning and sequence determination of the same hepatitis B viral genome.
- ~~Figure 3. Whole nucleotide sequence of human hepatitis B virus, isolated from HCC and carrying a mutation at amino acid residue 133 (Methionine to Threonine) of the major surface antigen (SEQ I.D. No. 1). The mutation is shown at nucleic acids numbered 551-553.~~

~~oligonucleotide) (SEQ.I.D.No.11).~~

DETAILED DESCRIPTION OF THE INVENTION

Throughout this application, references to specific nucleotides are to nucleotides present on the coding strand of the nucleic acid. The following standard abbreviations are used throughout the specification to indicate specific nucleotides:

C=cytosine	A=adenosine
T=thymidine	G=guanosine

The present invention provides the nucleotide sequence of human hepatitis B virus genome isolated from hepatocellular carcinoma (HCC), which carries a mutation at amino acid residue 133 (Methionine to Threonine) of the major surface antigen, consisting of 3215 nucleotides (Figure 3) coding for 4 overlapping viral proteins shown in Figures 4-7.

The invention provides the amino acid sequences of the four major viral proteins, including the DNA polymerase, large/middle/major surface antigen, core and trans-activating X. These proteins can be produced using recombinant technology, and used in developing polyclonal or monoclonal antibodies.

The present invention also provides a human hepatitis B virus diagnostic system, specific for the mutation at amino acid residue 133 (Methionine to Threonine) of the major surface antigen, using the nucleotide or protein sequences, or antibodies described above.

This invention provides an isolated strain of Hepatitis B virus designated Human Hepatitis B Virus Surface Antigen-'S'-133 Oon Strain (Methionine to Threonine) which constituent viral genome is deposited under Accession Nos. P97121501, P97121502 and P97121503.

This invention also provides an isolated nucleic acid encoding

a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine rather than a methionine. In a specific embodiment, the polypeptide is being encoded by nucleotides 155 through 835 of the nucleic acid sequence designated SEQ. I.D. No. 1, comprising nucleotides "ATG" in position 551-553, instead of "ACG."

The isolated nucleic acid can be DNA or RNA, specifically cDNA or genomic DNA.

- 15 In another embodiment, the polypeptide has an amino acid sequence substantially identical to amino acid residues 174 through 400 of the amino acid sequence designated SEQ. I.D. No. 3.
- 20 This invention also provides an isolated nucleic acid which encodes a peptide, wherein the peptide is encoded by a nucleic acid molecule comprising nucleotides 527 through 595 of SEQ I.D. No. 1.
- 25 This invention also provides an isolated nucleic acid which encodes a peptide, wherein the peptide has an amino acid sequence comprising amino acid residues 298 through 320 of the amino acid sequence designated SEQ. I.D. No. 3.
- 30 This invention further provides a vector comprising an isolated nucleic acid encoding a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine rather than a methionine and operatively linked to a promoter of RNA transcription.

This Sheet Has Been Replaced

SUBSTITUTE SHEET (RULE 26)

This invention further provides a vector comprising an isolated nucleic acid encoding a peptide, wherein the peptide is encoded by a nucleic acid molecule comprising nucleotides 527 through 595 of SEQ. I.D. No. 1.

5

Specifically the vectors above comprise viral DNA.

This invention also provides a host vector system for the production of a polypeptide or peptide and comprises the above-identified vectors in a suitable host.

10

Also in this invention, is a method of producing a polypeptide which comprises growing in the host vector systems described above, under suitable conditions permitting production of the polypeptide or the peptide and recovering the polypeptide or peptide.

15

This invention also provides a method of obtaining a polypeptide or peptide in purified form which comprises:

(a) introducing any of the above-describes vectors into a suitable host cell; (b) culturing the resulting host cell so as to produce the polypeptide; (c) recovering the polypeptide produced into step (b); and (d) purifying the polypeptide or peptide so recovered.

25

This invention also provides a purified polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine rather than a methionine. Specifically, one can obtain the purified polypeptide or peptide using the above methods.

30

This invention provides a purified peptide, wherein the peptide has an amino acid sequence comprising amino acid residues 298 through 320 of the amino acid sequence designated SEQ. I.D. No. 3.

35

This invention also provides an oligonucleotide of at least 15 nucleotides capable of specifically hybridizing with a unique sequence of nucleotides within a nucleic acid which encodes a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine rather than a methionine, without hybridizing to any sequence of nucleotides within a nucleic acid which encodes the major surface antigen of a wildtype hepatitis B virus. In an embodiment, the oligonucleotide comprises nucleotides 527 through 595 of SEQ. I.D. No. 1.

This invention also provides a composition capable of stimulating or enhancing antibody production for the polypeptide.

This invention also provides a method of obtaining antibodies to a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine, and not to the major surface antigen of a wild type hepatitis B virus, comprising:

- (a) obtaining the polypeptide in a purified form;
- (b) immunizing an organism capable of producing antibodies against the purified polypeptide;
- (c) collecting the produced antibodies;
- (d) combining the produced antibodies and the purified polypeptide under conditions to form a complex; and
- (e) determining which produced antibodies form a complex with the purified polypeptide so as to obtain antibodies to the polypeptide.

In a specific embodiment, the polypeptide is being encoded by nucleotides 155 through 835 of the nucleic acid sequence designated SEQ. I.D. No. 1. In another embodiment, the polypeptide has an amino acid sequence substantially identical to amino acid residues 174 through 400

of the amino acid sequence designated SEQ. I.D. No. 3.

One can obtain these antibodies from organism such as a rabbit or a mouse.

5

This invention also provides a method of obtaining antibodies to a peptide, wherein the peptide has an amino acid sequence comprising amino acid residues 298 through 320 of the amino acid sequence designated SEQ. I.D. No. 3, comprising: (a) obtaining the peptide in a purified form; (b) immunizing an organism capable of producing antibodies against the purified peptide; (c) collecting the produced antibodies; (d) combining the produced antibodies and the purified peptide under conditions to form a complex; and (e) determining which produced antibodies form a complex with the purified peptide so as to obtain antibodies to the peptide.

10

15

This invention also provides for the antibodies obtained using the methods described above, specifically when the antibodies are monoclonal antibodies.

20

This invention also provides for antibodies capable of detecting a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine, and incapable of detecting the major surface antigen of a wild type hepatitis B virus.

25

30

This invention further provides for antibodies capable of detecting a peptide, wherein the peptide has an amino acid sequence comprising amino acid residues 298 through 320 of the amino acid sequence designated SEQ. I.D. No. 3.

35

This invention provides use of a nucleic acid encoding a polypeptide which is a mutant major surface antigen of a

strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine for determining whether a subject is infected with a strain of Hepatitis B virus designated Human Hepatitis B Virus Surface Antigen-'S'-133 Oon Strain (Methionine to Threonine), wherein such determination comprises: (a) obtaining an appropriate nucleic acid sample from the subject; and (b) determining whether the nucleic acid sample from step (a) is, or is derived from, a nucleic acid encoding a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine.

In one embodiment, the nucleic acid sample in step (a) comprises mRNA corresponding to the transcript of DNA encoding a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine, and wherein the determining of step (b), which comprises: (i) contacting the mRNA with the oligonucleotide under conditions permitting binding of the mRNA to the oligonucleotide so as to form a complex; (ii) isolating the complex so formed; and (iii) identifying the mRNA in the isolated complex so as to thereby determine whether the mRNA is, or is derived from, a nucleic acid which encodes the polypeptide.

In another embodiment, the nucleic acid sample in step (a) comprises mRNA corresponding to the transcript of DNA encoding a polypeptide which is a mutant major surface antigen of a

strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine, and wherein the determining of step (b) comprises: (i) translating the mRNA under suitable conditions to obtain an amino acid sequence; and (ii) comparing the amino acid sequence of step (i) with the amino acid sequence encoded by the above-described isolated nucleic acid so as to thereby determine whether the nucleic acid sample is, or is derived from, a nucleic acid which encodes the polypeptide.

Further, one can determine step (b) by: (i) amplifying the nucleic acid present in the sample of step (a); and (ii) detecting the presence of polypeptide in the resulting amplified nucleic acid.

This invention also provides use of antibodies that recognize a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine for determining whether a subject is infected with a strain of Hepatitis B virus designated Human Hepatitis B Virus Surface Antigen-'S'-133 Oon Strain (Methionine to Threonine), wherein such determination comprises: (a) obtaining an appropriate sample from the subject; and (b) determining whether the sample from step (a) is, or is derived from, a nucleic acid encoding a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine by contacting the sample under appropriate conditions to bind to the antibodies

recognizing the polypeptide so as to determine whether a subject is infected.

5 In the above-identified uses, the isolated nucleic acid, oligonucleotide or antibody may be labeled with a detectable marker. Examples of detectable markers include radioactive isotopes, fluorophors, and enzymes.

10 In embodiments, the sample may comprise blood, tissue or sera.

15 This invention provides use of a nucleic acid encoding a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine for determining whether a subject has a predisposition for hepatocellular carcinoma, wherein such determination comprises: (a) obtaining an appropriate nucleic acid sample from the subject; and (b) determining whether the nucleic acid sample from step (a) is, or is derived from, a nucleic acid encoding a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine.

30 In one embodiment, the nucleic acid sample in step (a) comprises mRNA corresponding to the transcript of DNA encoding a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine, and wherein the determining of step (b), which comprises: (i) contacting the

mRNA with the oligonucleotide under conditions permitting binding of the mRNA to the oligonucleotide so as to form a complex; (ii) isolating the complex so formed; and (iii) identifying the mRNA in the isolated complex so as to thereby
5 determine whether the mRNA is, or is derived from, a nucleic acid which encodes the polypeptide.

In another embodiment, the nucleic acid sample in step (a) comprises mRNA corresponding to the transcript of DNA encoding
10 a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is
15 a threonine, rather than a methionine, and wherein the determining of step (b) comprises: (i) translating the mRNA under suitable conditions to obtain an amino acid sequence; and (ii) comparing the amino acid sequence of step (i) with the amino acid sequence of the isolated nucleic acid which
20 encodes a polypeptide, wherein the polypeptide has an amino acid sequence substantially identical to amino acids 174 through 400 of the amino acid sequence designated SEQ. I.D. No. 3, so as to thereby determine whether the nucleic acid sample is, or is derived from, a nucleic acid which encodes
25 the polypeptide.

In another embodiment, the determining of step (b) comprises: (i) amplifying the nucleic acid present in the sample of step (a); and (ii) detecting the presence of polypeptide in the
30 resulting amplified nucleic acid.

This invention further provides use of antibodies that recognize a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide
35 having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a

methionine for determining whether a subject has a predisposition for hepatocellular carcinoma, wherein such determination comprises: (a) obtaining an appropriate sample from the subject; and (b) determining whether the sample from
5 step (a) is, or is derived from, a nucleic acid encoding a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that
10 the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine by contacting the sample under appropriate conditions to bind to the antibodies that recognize the polypeptide so as to determine whether a subject is infected.

15 In the above-described uses, the isolated nucleic acid, oligonucleotide or antibody may be labeled with a detectable marker. Examples of detectable markers include radioactive isotopes, fluorophors, and enzymes.

20 In embodiments, the sample may comprise blood, tissue or sera.

This invention provides a method for identifying a chemical compound for the manufacture of a medicament which is capable
25 of treating infection by a strain of Hepatitis B virus designated Human Hepatitis B Virus Surface Antigen-'S'-133 Oon Strain (Methionine to Threonine) which comprises: (a) contacting a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide
30 having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine, with the chemical compound under conditions
35 permitting binding between the polypeptide and the chemical compound; (b) detecting specific binding of the chemical compound to the polypeptide; and (c) determining whether the chemical compound inhibits the polypeptide so as to identify

a chemical compound which is capable of treating infection by the viral strain.

This invention also provides a method for identifying a chemical compound for the manufacture of a medicament which is capable of preventing infection by a strain of Hepatitis B virus designated Human Hepatitis B Virus Surface Antigen-'S'-133 Oon Strain (Methionine to Threonine), which comprises: (a) contacting a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine, with the chemical compound under conditions permitting binding between the polypeptide and the chemical compound; (b) detecting specific binding of the chemical compound to the polypeptide; and (c) determining whether the chemical compound inhibits the polypeptide so as to identify a chemical compound which is capable of preventing infection by the viral strain.

This invention also provides a method for identifying a chemical compound for the manufacture of a medicament which is capable of treating hepatocellular carcinoma which comprises: (a) contacting a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine, with the chemical compound under conditions permitting binding between the polypeptide and the chemical compound; (b) detecting specific binding of the chemical compound to the polypeptide; and (c) determining whether the chemical compound inhibits the polypeptide so as to identify a chemical compound which is capable of treating infection by the viral strain.

This invention also provides a method for identifying a chemical compound for the manufacture of a medicament which is capable of preventing hepatocellular carcinoma, which comprises: (a) contacting a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine, with the chemical compound under conditions permitting binding between the polypeptide and the chemical compound; (b) detecting specific binding of the chemical compound to the polypeptide; and (c) determining whether the chemical compound inhibits the polypeptide so as to identify a chemical compound which is capable of preventing infection by the viral strain.

This invention also provides a composition comprising the chemical compound identified by the above-described methods in an amount effective to treat or prevent infection by the strain and a pharmaceutically effective carrier.

This invention provides a composition comprising a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine, or derivative thereof, the amounts of such polypeptide being effective to stimulate or enhance antibody production in a subject, and a pharmaceutically acceptable carrier.

The actual effective amount will be based upon the size of the polypeptide, the biodegradability of the polypeptide, the bioactivity of the polypeptide and the bioavailability of the polypeptide. If the polypeptide does not degrade quickly, is bioavailable and highly active, a smaller amount will be

required to be effective. The effective amount will be known to one of skill in the art; it will also be dependent upon the form of the polypeptide, the size of the polypeptide and the bioactivity of the polypeptide. Use of an adjuvant for example, would lower the required amount of the polypeptide. One of skill in the art could routinely perform empirical activity tests to determine the bioactivity in bioassays and thus determine the effective amount.

Pharmaceutically acceptable carriers are well known to those skilled in the art and include, but are not limited to, 0.01-0.1M and preferably 0.05M phosphate buffer or 0.8% saline. Additionally, such pharmaceutically acceptable carriers may be aqueous or non-aqueous solutions, suspensions, and emulsions. Examples of non-aqueous solvents are propylene glycol, polyethylene glycol, vegetable oils such as olive oil, and injectable organic esters such as ethyl oleate. Aqueous carriers include water, alcoholic/aqueous solutions, emulsions or suspensions, including saline and buffered media. Parenteral vehicles include sodium chloride solution, Ringer's dextrose, dextrose and sodium chloride, lactated Ringer's or fixed oils. Intravenous vehicles include fluid and nutrient replenishers, electrolyte replenishers such as those based on Ringer's dextrose, and the like. Preservatives and other additives may also be present, such as, for example, antimicrobials, antioxidants, chelating agents, inert gases and the like.

This invention also provides a composition comprising a peptide, wherein the peptide has an amino acid sequence comprising amino acid residues 298 through 320 of the amino acid sequence designated SEQ. I.D. No. 3. or derivative thereof, the amounts of such peptide being effective to stimulate or enhance antibody production in a subject, and a pharmaceutically acceptable.

This invention also provides compositions comprising the chemical compound identified by the above-described methods in

an amount effective to treat or prevent hepatocellular carcinoma and a pharmaceutically effective carrier.

5 This invention also provides a composition comprising the chemical compound identified by the above-described methods in an amount effective to treat or prevent infection by a strain of hepatitis B virus designated Human Hepatitis B Virus Surface Antigen-'S'-133 Oon Strain (Methionine to Threonine) and a pharmaceutically effective carrier.

10

This invention further provides use of the above-identified compositions for treating a subject infected with a strain of Hepatitis B virus designated Human Hepatitis B Virus Surface Antigen-'S'-133 Oon Strain (Methionine to Threonine).

15

This invention also provides use of the above-identified compositions for preventing infection by a strain of Hepatitis B virus designated Human Hepatitis B Virus Surface Antigen-'S'-133 Oon Strain (Methionine to Threonine) in a subject.

20

This invention also provides use of the above-described compositions for treating or preventing hepatocellular carcinoma.

25 This invention also provides a method of screening bodily fluids from a subject for a strain of hepatitis B virus designated Human Hepatitis B Virus Surface Antigen-'S'-133 Oon Strain (Methionine to Threonine) which comprises: (a) obtaining an appropriate sample of bodily fluid from the
30 subject; (b) determining the presence of a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino
35 acid at position number 133 of such polypeptide is a threonine, rather than a methionine in the sample of step (a) so as to screen the sample for the strain. Specifically, wherein the bodily fluid comprises blood, sera, or a nucleic

acid sample of blood or sera.

This invention further provides a method of treating a subject infected with this viral strain.

5

This invention also provides a method of screening tissues and bodily fluids for this viral strain.

10

This invention provides a hepatitis vaccine, comprising a mutant form of the surface antigen of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the wild type amino acid sequence of the major surface antigen of hepatitis B in that the amino acid at position number 133 of such polypeptide is a threonine rather than a methionine.

15

This invention also provides the above-described vaccine, further comprising an adjuvant.

20

This invention is illustrated in the Experimental Details section which follows. These sections are set forth to aid in an understanding of the invention but are not intended to, and should not be construed to, limit in any way the invention as set forth in the claims which follow thereafter.

Experimental Details

In the method described below, the human hepatitis B virus carrying the mutation at amino acid residue 133 (Methionine to Threonine) of the major surface antigen was isolated, and its nucleotide sequence was determined.

Serum sample (5194) was obtained from a 63-year old Chinese female patient of surface antigen carrier. She was confirmed as a HCC patient by subsequent biopsy. The hepatitis B virus from her serum carried a mutation at amino acid residue 133 (Methionine to Threonine) in the major surface antigen, as shown by previous sequencing analysis of the "a" epitope. Viral DNA was extracted prior to the determination of its sequence in the present invention.

As described in the examples below, the genome of this hepatitis B mutant virus from HCC and carrying a mutation at the amino acid residue 133 of the major surface antigen, consists of 3215 nucleotides which is identical to that of the wild type virus of the same subtype (adr). Open reading frames (ORF) coding for the major viral proteins are found at corresponding positions when compared to the wild type virus. Position 1 in the mutant hepatitis B virus genome is defined according to that in the wild type virus.

The structure of the different ORFs in the mutant human virus genome are reported here and summarized in Fig. 1. The locations are indicated as follows:

- DNA polymerase gene starts at position 2307 and ends at position 1623, therefore consisting of 2532 nucleotides and coding for 843 amino acid residues;
- Large surface antigen gene starts at position 2848 and ends at position 835, therefore consisting of 1203 nucleotides and coding for 400 amino acid residues. This large surface antigen overlaps the middle surface antigen which starts at position 3205 and the major surface antigen which starts at position 155. Both the middle (consisting of 281 amino acids

residues) and the major (consisting of 226 amino acid residues) surface antigens end at the same position as the large surface antigen;

- Core gene starts at position 1814 and ends at position 2452, therefore consisting of 639 nucleotides and coding for 212 amino acid residues; and

- Trans-activating X gene starts at position 1374 and ends at position 1838, therefore consisting of 465 nucleotides and coding for 154 amino acid residues.

10

Furthermore, sequence analysis has established this mutant hepatitis B virus belongs to the adr subtype as indicated by a lysine residue and an arginine residue at positions 122 and 160 respectively in the major surface antigen. Consistent with previous analysis of the "a" epitope by direct sequencing, the mutation (from Methionine to Threonine) is found at amino acid residue 133 of the major surface antigen.

Compared with the wild type hepatitis B virus deposited in the Genbank database (accession number D16665), the identity of this hepatitis B viral strain is at 90.3% for the nucleotide sequence. The identity of different viral proteins of the present mutant hepatitis B virus as compared with its counterpart, the wild type virus, is 95.8%, 97.5%, 95.1% and 94.8% for DNA polymerase (PIR - Protein Identification Resources accession number S43491), large surface antigen (PIR accession number JQ2107), core (PIR accession number S43490) and trans-activating X (PIR accession number S35529) proteins respectively. Conversely, numerous amino acid substitutions are present in each of the viral proteins as compared to their wild type counterparts, these include: 5 mutations in DNA polymerase, 5 in large surface antigen (including the Methionine to Threonine change for the initiation codon of the major surface antigen), 5 in core and 4 in trans-activating X protein.

35

The human hepatitis B virus genome in the present invention, isolated from HCC and carrying mutation at amino acid residue

133 (Methionine to Threonine) of the major surface antigen, can be used as material to design oligonucleotides specific to the mutant virus genome. These oligonucleotides can be used as material for highly specific diagnostic agents that detect virus derived from HCC carrying a mutation at amino acid residue 133 of the major surface antigen.

The human hepatitis B virus genome in the present invention, with a mutation at amino acid residue 133 (Methionine to Threonine) of the major surface antigen, can be used as material to produce proteins of the invention by expressing a vector that carries the relevant coding region, and which can replicate in a host cell such as Escherichia coli by standard DNA recombinant technology.

Proteins of the present invention are useful as material for highly specific diagnostic agents capable of detecting hepatitis B virus from HCC, carrying a mutation at amino acid residue 133 (Methionine to Threonine) of the major surface antigen. Using known methods, these same proteins can be used to produce polyclonal and monoclonal antibodies.

Polyclonal and monoclonal antibodies can be used as material for diagnostic agents to detect with high specificity antigens of hepatitis B virus, from HCC, with a mutation at amino acid residue 133 (Methionine to Threonine) of the major surface antigen.

A detection system using each protein of the present invention or proteins with partial replacement of amino acids, and a detection system using monoclonal or polyclonal antibodies to such proteins are useful as highly specific diagnostic agents capable of detecting of human hepatitis B virus from HCC to detect this virus from patients who are carriers of hepatitis B surface antigen who may then be at risk of developing HCC. The proteins, or antibodies of such proteins can be used as a material for development of prophylactic and therapeutic vaccines against this viral strain.

It is well known that one or more nucleotides in a DNA sequence can be substituted by other nucleotides to produce the same protein. The present invention also concerns such nucleotide changes which code for proteins reported in this invention. It is equally well known that one or more amino acids in a protein sequence can be replaced by other analogous amino acids, as defined by their hydrophilic properties or charges, to produce an analog of the amino acid sequence. Any analogs of the proteins of the present invention involving amino acid replacement, deletions, isosteres (modified amino acids that bear close structural and spatial similarity to protein amino acids), or additions, can be utilized, provided that the resulting sequences elicit antibodies recognizing hepatitis B virus from HCC with a mutation at amino acid mutation 133 (Methionine to Threonine) of the major surface antigen.

EXAMPLES

The nucleotide sequence and the deduced amino acid sequence of human hepatitis B virus, isolated from HCC and carrying a mutation at amino acid residue 133 (Methionine to Threonine) of the major surface antigen, were determined in the following manner:

1. Isolation of Viral DNA

The viral DNA was isolated from a serum sample (5194) obtained from a 63-year old Chinese female patient of surface antigen carrier. She was confirmed as an HCC patient by biopsy. The hepatitis B virus from her serum carried a mutation at amino acid residue 133 (Methionine to Threonine) in the major surface antigen, as shown by our previous sequencing analysis of the "a" epitope.

The isolation method used was:

200 μ l of the serum sample was added with 400 μ l of the lysis buffer (Tris chloride 10 mM, pH7.4, EDTA 1 mM, and sodium

dodecyl sulfate 2%) and 25 μ l of proteinase K (20 mg/ml), incubated at 65⁰ C for 3 hours. Viral DNA was then extracted by phenol/chloroform and precipitated by ethanol.

5 2. Amplification of Viral DNA by Polymerase Chain Reaction (PCR)

The virus genome in the present invention was amplified by polymerase chain reaction (PCR) using 3 sets of overlapping
10 oligonucleotides, which were designed according to the wild type hepatitis B virus. Various restriction enzyme sites were included to facilitate the cloning of the PCR products. The position of these oligonucleotides is shown in Fig. 2 and indicated as follows:

- 15 - Flag 1 (ATAAGCTTATGCCCTATCTTATCAACACTTCCGGA) (SEQ. I.D. No. 6) starts at the initiation site of the coding region of DNA polymerase, at position 2307 of the viral nucleotide sequence and matches the coding strand (sense oligonucleotide). An additional HindIII restriction enzyme site is underlined;
- 20 - Xba3 (GAGTCTAGACTCTGCGGTATTGTGA) (SEQ. I.D. No. 7) starts at the internal restriction enzyme site XbaI, at position 250 of the viral nucleotide sequence and matches the complementary strand (anti-sense oligonucleotide). An additional XbaI restriction enzyme site is underlined;
- 25 - Xba5 (GAGTCTAGACTCGTGGTGGACTTCT) (SEQ. I.D. No. 8) starts at the internal XbaI site, at the same location as that of Xba3 oligonucleotide but matches the coding strand (sense oligonucleotide). An additional XbaI restriction enzyme site is underlined;
- 30 - Common 3 (TGAGAATTCTCACGGTGGTCTCCATGCGACGT) (SEQ. I.D. No. 9) starts at the stop codon of the DNA polymerase, at position 1623 of the viral nucleotide sequence and matches the complementary strand (anti-sense oligonucleotide). An additional EcoRI restriction enzyme site is underlined;
- 35 - V11 (TTTGTTTACGTCCCGT) (SEQ. I.D. No. 10) starts near the initiation site of the X gene, at position 1420 of the viral nucleotide sequence and matches the coding strand (sense oligonucleotide);

- HindIIIADW3 (CTAAGCTTAGTTTCCGGAAGTGTGAT) (SEQ. I.D. No. 11) starts close to the initiation site of the DNA polymerase, at position 2340 and matches the complementary strand (anti-sense oligonucleotide). An additional Hind III restriction enzyme site is underlined.

Using viral DNA as template, PCR was then carried out on a DNA Thermal Cycler (Perkin-Elmer. Cetus) for 35 cycles using Pfu polymerase (Stratagene, U.S.A.), each cycle consisting of 1.5 minutes at a denaturing temperature of 94° C, 2 minutes at an annealing temperature of 53° C and 4 minutes at an extension temperature of 72° C. The following combinations of oligonucleotides were used; Flag1/Xba3, Xba5/Common3 and V11/HindIIIADW3, and generated amplification products of 1.2 kb, 1.4 kb and 1.1 kb respectively.

3. Cloning of the Amplified Viral DNA Fragments

The amplified viral DNA fragment from Flag1/Xba3 (1.2 kb) was subjected to restriction enzyme digestion by HindIII and XbaI, prior to cloning in a BlueScript plasmid pre-treated by the same restriction enzymes. Similar digestion with XbaI and EcoRI was applied to PCR product from Xba5/Common3 (1.4 kb), prior to cloning in a BlueScript plasmid pre-treated by XbaI and EcoRI. On the other hand, the DNA fragment amplified with V11 and HindIIIADW3 (1.1 kb) was directly cloned into a ZeroBlunt plasmid, developed by InvitroGen (U.S.A.) for cloning blunt-end DNA fragments.

4. Determination of Nucleotide Sequence

Nucleotide sequence of the human hepatitis B virus isolated from HCC and reported in the present invention was determined on plasmid DNA template by chain-terminating inhibitors, using the Sequenase DNA Sequencing Kit (United States Biochemical Corp.). To facilitate the sequencing procedure, various internal oligonucleotides were designed (from V1 to V16) according to the wild type hepatitis B virus, and their

positions are indicated in Figure 2.

From the analysis described above, the full-length nucleotide sequence of the hepatitis B virus, isolated from HCC and carrying a mutation at amino acid residue 133 (Methionine to Threonine) of the major surface antigen, was determined as shown in Figure 3. The deduced amino acid sequences coding for the major viral proteins are shown in Figures 4-7: hepatitis B viral DNA polymerase (Figure 4), the large surface antigen, including the middle and major surface antigen (Figure 5), the core protein (Figure 6) and the trans-activating X protein (Figure 7).

Alignment of the virus sequence in the present invention with other hepatitis B viral sequences, available in the Genbank database, will point to specific sequence differences which in turn can be used to design DNA probes. A detection system using polymerase chain reaction (PCR) can then be developed. Such PCR reactions will involve combinations of oligonucleotides specific to human hepatitis B virus in the present invention, with a mutation at the amino acid residue 133 (Methionine to Threonine) of the major surface antigen, thereby allowing highly specific detection of these mutant viral DNA. Briefly, viral DNA can be extracted as described in this invention. PCR reaction can be performed using specific oligonucleotides using the similar cycling conditions described above. Results can then be analyzed after resolving PCR products on a 1% agarose gel.

According to known immunological procedures, it is possible to determine epitopes from protein sequences as those in Figures 4-7. Determination of these epitopes specific to human hepatitis B virus, from HCC and carrying a mutation at amino acid residue 133 (Methionine to Threonine) of the major surface antigen, will allow synthesis of peptides using known genetic engineering methods, synthesis of proteins, production of antibodies specific to these epitopes, development of specific diagnostic reagents, development of prophylactic and

therapeutic vaccines, and antiviral agents.

A detection system for antibody against hepatitis B virus isolated from HCC and carrying a mutation at amino acid residue 133 (Methionine to Threonine) of the major surface antigen can be developed using polyvinyl microtiter plates and the sandwich method. Briefly, 50 μ l of 5 μ g/ml concentration of a peptide from the hepatitis B virus in the present invention, isolated from HCC and carrying a mutation at amino acid residue 133 (Methionine to Threonine) of the major surface antigen, can be dispensed in each well of the microtiter plates and incubated overnight at room temperature for consolidation. A similar procedure can be applied to a protein purified from host cells such as Escherichia coli. The microplate wells can be washed five times with physiological saline solution containing 0.05% Tween 20. For overcoating, 100 μ l of NaCl buffer containing 30% (v/v) of calf serum and 0.05% Tween 20 (CS buffer) can be dispensed in each well and discarded after incubation for 30 minutes at room temperature.

To determine antibodies specific for the mutant (Methionine to Threonine at amino acid residue 133 of the major surface antigen) hepatitis B virus in serum, the primary reaction can be carried out such that 50 μ l of the CS buffer and 10 μ l of a serum sample can be dispensed in each microplate well and incubated on a microplate vibrator for one hour at room temperature. After completion of the primary reaction, microplate wells are washed five times as described above.

In the secondary reaction, 1 ng of horseradish peroxidase labeled anti-human IgG mouse monoclonal antibodies dissolved in 50 μ l of calf serum can be dispensed in each microplate well and incubated on a microplate vibrator for one hour at room temperature. Upon completion, wells can be washed five times in the same way. After addition of hydrogen peroxide (as substrate) and 50 μ l of O-phenylenediamine solution (as color developer) in each well, and after incubation for 30

minutes at room temperature, 50 μ l of 4M sulphuric acid solution can be dispensed in each well to stop further color development and for reading absorbance at 490nm.

- 5 The present invention makes possible detection of the mutant human hepatitis B virus, in particular those carrying a mutation at amino acid residue 133 (Methionine to Threonine) of the major surface antigen. The present invention also provides detection systems capable of a highly specific and
10 sensitive detection at an early stage of infection or development of HCC when the HCC may be treated and cured.

In addition, these features allow accurate diagnosis of patients at an early stage in the HCC and also help to inhibit
15 with higher efficiency mutant hepatitis B virus.

Proteins and their antibodies under the present invention can be utilized for development of prophylactic and therapeutic vaccines, as well as, immunological pharmaceuticals. Sequence
20 information on structural genes of these mutant viruses will be helpful for developing detection systems of the relevant protein antigens and antibodies.

Antigen-antibody complexes can be detected by known methods.
25 Specific monoclonal and polyclonal antibodies can be raised by immunizing animals such as mice and rabbits with peptides or proteins specific to mutant hepatitis B viruses from HCC. Inhibitory antiviral agents can be designed and targeted against these proteins and molecules in cell culture or in
30 vivo.

The present invention is based on studies on human hepatitis virus genome isolated from HCC and carrying a mutation at amino acid residue 133 (Methionine to Threonine) of the major
35 surface antigen. The invention makes possible highly specific detection of these mutant hepatitis B virus from HCC, and provides material such as protein, polyclonal and monoclonal antibodies for development of such detection system.

ATAAGCTTAT GCCCCTATCT TATCAACACT TCCGGA

36

What is claimed is:

1. An isolated strain of Hepatitis B virus designated Human Hepatitis B Virus Surface Antigen-'S'-133 Oon Strain (Methionine to Threonine) which constituent viral genome is deposited under Accession Nos. P97121501, P97121502 and P97121503 with the European Collection of Cell Culture on 15th December 1997.
2. An isolated nucleic acid encoding a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine rather than a methionine.
3. The isolated nucleic acid of claim 2, wherein the polypeptide is being encoded by nucleotides 155 through 835 of the nucleic acid sequence designated SEQ. I.D. No. 1.
4. The isolated nucleic acid of claim 3, comprising nucleotides "ACG" in position 551-553.
5. The isolated nucleic acid of claim 2, wherein the nucleic acid is DNA.
6. The isolated nucleic acid of claim 2, wherein the nucleic acid is RNA.
7. The isolated nucleic acid of claim 5, wherein the nucleic acid is cDNA.
8. The isolated nucleic acid of claim 5, wherein the nucleic acid is genomic DNA.

This Sheet Has Been Replaced

SUBSTITUTE SHEET (RULE 26)

9. The isolated nucleic acid of claim 2, wherein the polypeptide has an amino acid sequence substantially identical to amino acid residues 174 through 400 of the amino acid sequence designated SEQ. I.D. No. 3.
- 5
10. An isolated nucleic acid which encodes a peptide, wherein the peptide is encoded by a nucleic acid molecule comprising nucleotides 527 through 595 of SEQ. I.D. No. 1.
- 10
11. An isolated nucleic acid which encodes a peptide, wherein the peptide has an amino acid sequence comprising amino acid residues 298 through 320 of the amino acid sequence designated SEQ. I.D. No. 3.
- 15
12. A vector comprising an isolated nucleic acid encoding a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine rather than a methionine and operatively linked to a promoter of RNA transcription.
- 20
13. A vector comprising an isolated nucleic acid encoding a peptide, wherein the peptide is encoded by a nucleic acid molecule comprising nucleotides 527 through 595 of SEQ. I.D. No. 1.
- 25
14. The vector of claim 12 or 13, wherein the vector comprises viral DNA.
- 30
15. A host vector system for the production of a polypeptide which comprises the vector of claim 12 in a suitable host.
- 35
16. A host vector system for the production of a peptide

SUBSTITUTE SHEET (RULE 26)

This Sheet Has Been Replaced

which comprises the vector of claim 13 in a suitable host.

- 5 17. A method of producing a polypeptide, which comprises growing the host vector system of claim 15 under suitable conditions permitting production of the polypeptide and recovering the polypeptide so produced.
- 10 18. A method of producing a peptide, which comprises growing the host vector system of claim 16 under suitable conditions permitting production of the polypeptide and recovering the polypeptide so produced.
- 15 19. A method of obtaining a polypeptide in purified form which comprises:
- (a) introducing the vector of claim 12 into a suitable host cell;
 - (b) culturing the resulting host cell so as to produce the polypeptide;
 - 20 (c) recovering the polypeptide produced into step (b); and
 - (d) purifying the polypeptide so recovered.
- 25 20. A method of obtaining a peptide in purified form which comprises:
- (a) introducing the vector of claim 13 into a suitable host cell;
 - (b) culturing the resulting host cell so as to produce the polypeptide;
 - 30 (c) recovering the polypeptide produced into step (b); and
 - (d) purifying the polypeptide so recovered.
- 35 21. A purified polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid

SUBSTITUTE SHEET (RULE 26)

This Sheet Has Been Replaced

at position number 133 of such polypeptide is a threonine rather than a methionine.

- 5 22. A purified polypeptide obtained from the method of claim 19.
- 10 23. A purified peptide, wherein the peptide has an amino acid sequence comprising amino acid residues 298 through 320 of the amino acid sequence designated SEQ. I.D. No.: 3.
24. A purified polypeptide obtained from the method of claim 20
- 15 25. An oligonucleotide of at least 15 nucleotides capable of specifically hybridizing with a unique sequence of nucleotides within a nucleic acid which encodes a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine rather than a methionine, without hybridizing to any sequence of nucleotides within a nucleic acid which encodes the major surface antigen of a wild type hepatitis B virus.
- 20 26. The oligonucleotide of claim 25 comprising nucleotides 527 through 595 of SEQ. I.D. No. 1.
- 25 27. A method of obtaining antibodies to a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine, and not to the major surface antigen of a wild type hepatitis
- 30
- 35

SUBSTITUTE SHEET (RULE 26)

This Sheet Has Been Replaced

B virus, comprising:

- (a) obtaining the polypeptide in a purified form;
- (b) immunizing an organism capable of producing antibodies against the purified polypeptide;
- 5 (c) collecting the produced antibodies;
- (d) combining the produced antibodies and the purified polypeptide under conditions to form a complex; and
- (e) determining which produced antibodies form a complex with the purified polypeptide so as to
- 10 obtain antibodies to the polypeptide.

28. The method of claim 27, wherein the polypeptide is being encoded by nucleotides 155 through 835 of the nucleic acid sequence designated SEQ. I.D. No. 1.

15

29. The method of claim 27, wherein the polypeptide has an amino acid sequence substantially identical to amino acid residues 174 through 400 of the amino acid sequence designated SEQ. I.D. No. 3.

20

30. The method of claim 27, wherein the organism comprises a rabbit or a mouse.

25

31. A method of obtaining antibodies to a peptide, wherein the peptide has an amino acid sequence comprising amino acid residues 298 through 320 of the amino acid sequence designated SEQ. I.D. No. 3, comprising:

30

35

- (a) obtaining the peptide in a purified form;
- (b) immunizing an organism capable of producing antibodies against the purified peptide;
- (c) collecting the produced antibodies;
- (d) combining the produced antibodies and the purified peptide under conditions to form a complex; and
- (e) determining which produced antibodies form a complex with the purified peptide so as to obtain antibodies to the peptide.

32. The method of claim 31, wherein the organism comprises

SUBSTITUTE SHEET (RULE 26)

This Sheet Has Been Replaced

a rabbit or a mouse.

33. The antibodies obtained in claim 27 or 31.
- 5 34. Monoclonal antibodies of the antibodies of claim 33.
35. Antibodies capable of detecting a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine, and incapable of detecting the major surface antigen of a wild type hepatitis B virus.
- 10 15
36. Antibodies capable of detecting a peptide, wherein the peptide has an amino acid sequence comprising amino acid residues 298 through 320 of the amino acid sequence designated SEQ. I.D. No. 3.
- 20
37. Use of a nucleic acid encoding a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine for determining whether a subject is infected with a strain of Hepatitis B virus designated Human Hepatitis B Virus Surface Antigen-'S'-133 Oon Strain (Methionine to Threonine), wherein such determination comprises:
- 25 30
- (a) obtaining an appropriate nucleic acid sample from the subject; and
- 35 (b) determining whether the nucleic acid sample from step (a) is, or is derived from, a nucleic acid encoding a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus,

SUBSTITUTE SHEET (RULE 26)

This Sheet Has Been Replaced

such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine.

38. The use of claim 37, wherein the nucleic acid sample in step (a) comprises mRNA corresponding to the transcript of DNA encoding a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine, and wherein the determining of step (b) comprises:
- (i) contacting the mRNA with the oligonucleotide of claim 25 under conditions permitting binding of the mRNA to the oligonucleotide so as to form a complex;
 - (ii) isolating the complex so formed; and
 - (iii) identifying the mRNA in the isolated complex so as to thereby determine whether the mRNA is, or is derived from, a nucleic acid which encodes the polypeptide.

39. The use of claim 37, wherein the nucleic acid sample in step (a) comprises mRNA corresponding to the transcript of DNA encoding a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine, and wherein the determining of step (b) comprises:
- (i) translating the mRNA under suitable conditions

SUBSTITUTE SHEET (RULE 26)

This Sheet Has Been Replaced

- to obtain an amino acid sequence; and
- (ii) comparing the amino acid sequence of step (i) with the amino acid sequence of the isolated nucleic acid of claim 9 so as to thereby determine whether the nucleic acid sample is, or is derived from, a nucleic acid which encodes the polypeptide.

40. The use of claim 37, wherein the determining of step (b) comprises:

- (i) amplifying the nucleic acid present in the sample of step (a); and
- (ii) detecting the presence of polypeptide in the resulting amplified nucleic acid.

41. Use of an antibody that recognizes a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine for determining whether a subject is infected with a strain of Hepatitis B virus designated Human Hepatitis B Virus Surface Antigen-'S'-133 Oon Strain (Methionine to Threonine), wherein such determination comprises:

- (a) obtaining an appropriate sample from the subject; and
- (b) determining whether the sample from step (a) is, or is derived from, a nucleic acid encoding a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine by contacting the sample under appropriate conditions to bind to

SUBSTITUTE SHEET (RULE 26)

This Sheet Has Been Replaced

the antibodies of claim 35 or 36 so as to determine whether a subject is infected.

- 5 42. The use of claim 37, 38 or 41, wherein the isolated nucleic acid, oligonucleotide or antibody is labeled with a detectable marker.
- 10 43. The use of claim 42, wherein the detectable marker is a radioactive isotope, a fluorophor or an enzyme.
44. The use of claim 37, wherein the sample comprises blood, tissue or sera.
- 15 45. Use of a nucleic acid encoding a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine for determining whether a subject has a predisposition for hepatocellular carcinoma, which comprises:
- 20 (a) obtaining an appropriate nucleic acid sample from the subject; and
- 25 (b) determining whether the nucleic acid sample from step (a) is, or is derived from, a nucleic acid encoding a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence
- 30 which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine.
- 35 46. The use of claim 45, wherein the nucleic acid sample in step (a) comprises mRNA corresponding to the transcript of DNA encoding a polypeptide which is a mutant major

SUBSTITUTE SHEET (RULE 26)

This Sheet Has Been Replaced

surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine, and wherein the determining of step (b), which comprises:

- (i) contacting the mRNA with the oligonucleotide of claim 25 under conditions permitting binding of the mRNA to the oligonucleotide so as to form a complex;
- (ii) isolating the complex so formed; and
- (iii) identifying the mRNA in the isolated complex so as to thereby determine whether the mRNA is, or is derived from, a nucleic acid which encodes the polypeptide.

47. The use of claim 45, wherein the nucleic acid sample in step (a) comprises mRNA corresponding to the transcript of DNA encoding a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine, and wherein the determining of step (b) comprises:

- (i) translating the mRNA under suitable conditions to obtain an amino acid sequence; and
- (ii) comparing the amino acid sequence of step (i) with the amino acid sequence of the isolated nucleic acid of claim 9 so as to thereby determine whether the nucleic acid sample is, or is derived from, a nucleic acid which encodes the polypeptide.

48. The use of claim 45, wherein the determining of step (b) comprises:

SUBSTITUTE SHEET (RULE 26)

This Sheet Has Been Replaced

- (i) amplifying the nucleic acid present in the sample of step (a); and
- (ii) detecting the presence of polypeptide in the resulting amplified nucleic acid.

5

49. Use of an antibody that recognizes a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine for determining whether the subject has a predisposition for hepatocellular carcinoma, wherein such determination comprises:

10

15

20

25

30

- (a) obtaining an appropriate sample from the subject; and
- (b) determining whether the sample from step (a) is, or is derived from, a nucleic acid encoding a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine by contacting the sample under appropriate conditions to bind to the antibodies of claim 35 or 36 so as to determine whether the subject has a predisposition for hepatocellular carcinoma.

35 50. The use of claim 46, 47 or 49, wherein the isolated nucleic acid, oligonucleotide or antibody is labeled with a detectable marker.

SUBSTITUTE SHEET (RULE 26)

This Sheet Has Been Replaced

51. The use of claim 50, wherein the detectable marker is a radioactive isotope, a fluorophor or an enzyme.
52. The use of claim 45, wherein the sample comprises blood, tissue or sera.
53. A method for identifying a chemical compound for the manufacture of a medicament which is capable of treating infection by a strain of Hepatitis B virus designated Human Hepatitis B Virus Surface Antigen-'S'-133 Oon Strain (Methionine to Threonine) which comprises:
- (a) contacting a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine, with the chemical compound under conditions permitting binding between the polypeptide and the chemical compound;
 - (b) detecting specific binding of the chemical compound to the polypeptide; and
 - (c) determining whether the chemical compound inhibits the polypeptide so as to identify a chemical compound which is capable of treating infection by the viral strain.
54. A method for identifying a chemical compound for the manufacture of a medicament which is capable of preventing infection by a strain of Hepatitis B virus designated Human Hepatitis B Virus Surface Antigen-'S'-133 Oon Strain (Methionine to Threonine), which comprises:
- (a) contacting a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a

SUBSTITUTE SHEET (RULE 26)

- 5 major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine, with the chemical compound under conditions permitting binding between the polypeptide and the chemical compound;
- (b) detecting specific binding of the chemical compound to the polypeptide; and
- 10 (c) determining whether the chemical compound inhibits the polypeptide so as to identify a chemical compound which is capable of preventing infection by the viral strain.

15 55. A method for identifying a chemical compound for the manufacture of a medicament which is capable of treating hepatocellular carcinoma which comprises:

- (a) contacting a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine, with the chemical compound under conditions permitting binding between the polypeptide and the chemical compound;
- 20 (b) detecting specific binding of the chemical compound to the polypeptide; and
- 25 (c) determining whether the chemical compound inhibits the polypeptide so as to identify a chemical compound which is capable of treating hepatocellular carcinoma.

35 56. A method for identifying a chemical compound for the manufacture of a medicament which is capable of preventing hepatocellular carcinoma, which comprises:

- (a) contacting a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus,

- 5 such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine, with the chemical compound under conditions permitting binding between the polypeptide and the chemical compound;
- 10 (b) detecting specific binding of the chemical compound to the polypeptide; and
- (c) determining whether the chemical compound inhibits the polypeptide so as to identify a chemical compound which is capable of preventing infection by the viral strain.
- 15
57. A composition comprising a polypeptide which is a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at position number 133 of such polypeptide is a threonine, rather than a methionine, or derivative thereof, the amounts of such polypeptide being effective to stimulate or enhance antibody production in a subject, and a pharmaceutically acceptable.
- 20
58. A composition comprising a peptide, wherein the peptide has an amino acid sequence comprising amino acid residues 298 through 320 of the amino acid sequence designated SEQ. I.D. No. 3. or derivative thereof, the amounts of such peptide being effective to stimulate or enhance antibody production in a subject, and a pharmaceutically acceptable.
- 30
59. A composition comprising the chemical compound identified by the method of claim 55 in an amount effective to treat hepatocellular carcinoma and a pharmaceutically effective carrier.
- 35

SUBSTITUTE SHEET (RULE 26)

- 5
60. A composition comprising the chemical compound identified by the method of claim 56 in an amount effective to prevent hepatocellular carcinoma and a pharmaceutically effective carrier.
- 10
61. A composition comprising the chemical compound identified by the method of claim 53 in an amount effective to treat a strain of hepatitis B virus designated Human Hepatitis B Virus Surface Antigen-'S'-133 Oon Strain (Methionine to Threonine) and a pharmaceutically effective carrier.
- 15
62. A composition comprising the chemical compound identified by the method of claim 54 in an amount effective to prevent infection by a strain of hepatitis B virus designated Human Hepatitis B Virus Surface Antigen-'S'-133 Oon Strain (Methionine to Threonine) and a pharmaceutically effective carrier.
- 20
63. Use of the composition of claim 57 or 58 for treating a subject infected with a strain of Hepatitis B virus designated Human Hepatitis B Virus Surface Antigen-'S'-133 Oon Strain (Methionine to Threonine).
- 25
64. Use of the composition of claim 61 treating a subject infected with a strain of hepatitis B virus designated Human Hepatitis B Virus Surface Antigen-'S'-133 Oon Strain (Methionine to Threonine).
- 30
65. Use of the composition of claim 57 or 58 for preventing infection by a strain of Hepatitis B virus designated Human Hepatitis B Virus Surface Antigen-'S'-133 Oon Strain (Methionine to Threonine) in a subject.
- 35
66. Use of the composition of claim 62 for preventing infection by a strain of Hepatitis B virus designated Human Hepatitis B Virus Surface Antigen-'S'-133 Oon Strain (Methionine to Threonine) in a subject.

SUBSTITUTE SHEET (RULE 26)

67. Use of the composition of claim 57 or 58 for treating a subject with hepatocellular carcinoma.
- 5 68. Use of the composition of claim 59 for treating a subject with hepatocellular carcinoma.
69. Use of the composition of claim 57 or 59 for preventing hepatocellular carcinoma in a subject.
- 10 70. Use of the composition of claim 60 for preventing hepatocellular carcinoma in a subject.
71. A method of screening bodily fluids from a subject for a strain of hepatitis B virus designated Human Hepatitis B Virus Surface Antigen-'S'-133 Oon Strain (Methionine to Threonine) which comprises:
- 15 (a) obtaining an appropriate sample of bodily fluid from the subject;
- (b) determining the presence of a polypeptide which is
- 20 a mutant major surface antigen of a strain of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the amino acid sequence of a major surface antigen of a wild type hepatitis B virus in that the amino acid at
- 25 position number 133 of such polypeptide is a threonine, rather than a methionine in the sample of step (a) so as to screen the sample for the strain.
- 30 72. The method of claim 71, wherein the bodily fluid comprises blood, sera, or a nucleic acid sample of blood or sera.
73. A hepatitis vaccine, comprising a mutant form of the
- 35 surface antigen of hepatitis B virus, such polypeptide having an amino acid sequence which differs from the wild type amino acid sequence of the major surface antigen of hepatitis B in that the amino acid at position number 133
