

**ALKYNYL PHENYL DERIVATIVE COMPOUNDS  
FOR TREATING OPHTHALMIC DISEASES AND DISORDERS**

**CROSS-REFERENCE**

- [0001] This application claims the benefit of U.S. Provisional Application No. 60/947,321, filed on June 29, 2007, which application is incorporated herein in its entirety by reference.

**BACKGROUND OF THE INVENTION**

- [0002] Neurodegenerative diseases, such as glaucoma, macular degeneration, and Alzheimer's disease, affect millions of patients throughout the world. Because the loss of quality of life associated with these diseases is considerable, drug research and development in this area is of great importance.
- [0003] Macular degeneration affects between ten and fifteen million patients in the United States, and it is the leading cause of blindness in aging populations worldwide. Age-related macular degeneration (AMD) affects central vision and causes the loss of photoreceptor cells in the central part of retina called the macula. Macular degeneration can be classified into two types: dry-type and wet-type. The dry-form is more common than the wet; about 90% of age-related macular degeneration patients are diagnosed with the dry-form. The wet-form of the disease and geographic atrophy, which is the end-stage phenotype of dry AMD, causes the most serious vision loss. All patients who develop wet-form AMD are believed to previously have developed dry-form AMD for a prolonged period of time. The exact causes of age-related macular degeneration are still unknown. The dry-form of AMD may result from the senescence and thinning of macular tissues associated with the deposition of pigment in the macular retinal pigment epithelium. In wet AMD, new blood vessels grow beneath the retina, form scar tissue, bleed, and leak fluid. The overlying retina can be severely damaged, creating "blind" areas in the central vision.
- [0004] For the vast majority of patients who have the dry-form of macular degeneration, no effective treatment is yet available. Because the dry-form precedes development of the wet-form of macular degeneration, therapeutic intervention to prevent or delay disease progression in the dry-form AMD would benefit patients with dry-form AMD and might reduce the incidence of the wet-form.
- [0005] Decline of vision noticed by the patient or characteristic features detected by an ophthalmologist during a routine eye exam may be the first indicator of age-related macular degeneration. The formation of "drusen," or membranous debris beneath the retinal pigment epithelium of the macula is often the first physical sign that AMD is developing. Late symptoms include the perceived distortion of straight lines and, in advanced cases, a dark, blurry area or area with absent vision appears in the center of vision; and/or there may be color perception changes.
- [0006] Different forms of genetically-linked macular degenerations may also occur in younger patients. In other maculopathies, factors in the disease are heredity, nutritional, traumatic, infection, or other ecologic factors.
- [0007] Glaucoma is a broad term used to describe a group of diseases that causes a slowly progressive visual field loss, usually asymptotically. The lack of symptoms may lead to a delayed diagnosis of glaucoma until the terminal stages of the disease. The prevalence of glaucoma is estimated to be 2.2 million in the United States, with about 120,000 cases of blindness attributable to the condition. The disease is particularly prevalent in Japan, which has four million reported cases. In many parts of the world, treatment is less accessible than in the United States and Japan, thus glaucoma ranks as a leading cause of blindness worldwide. Even if subjects afflicted with glaucoma do not become blind, their vision is often severely

impaired.

- [0008] The progressive loss of peripheral visual field in glaucoma is caused by the death of ganglion cells in the retina. Ganglion cells are a specific type of projection neuron that connects the eye to the brain. Glaucoma is usually accompanied by an increase in intraocular pressure. Current treatment includes use of drugs that lower the intraocular pressure; however, contemporary methods to lower the intraocular pressure are often insufficient to completely stop disease progression. Ganglion cells are believed to be susceptible to pressure and may suffer permanent degeneration prior to the lowering of intraocular pressure. An increasing number of cases of normal-tension glaucoma are observed in which ganglion cells degenerate without an observed increase in the intraocular pressure. Current glaucoma drugs only treat intraocular pressure and are ineffective in preventing or reversing the degeneration of ganglion cells.
- [0009] Recent reports suggest that glaucoma is a neurodegenerative disease, similar to Alzheimer's disease and Parkinson's disease in the brain, except that it specifically affects retinal neurons. The retinal neurons of the eye originate from diencephalon neurons of the brain. Though retinal neurons are often mistakenly thought not to be part of the brain, retinal cells are key components of the central nervous system, interpreting the signals from the light-sensing cells.
- [0010] Alzheimer's disease (AD) is the most common form of dementia among the elderly. Dementia is a brain disorder that seriously affects a person's ability to carry out daily activities. Alzheimer's is a disease that affects four million people in the United States alone. It is characterized by a loss of nerve cells in areas of the brain that are vital to memory and other mental functions. Currently available drugs can ameliorate AD symptoms for a relatively period of time, but no drugs are available that treat the disease or completely stop the progressive decline in mental function. Recent research suggests that glial cells that support the neurons or nerve cells may have defects in AD sufferers, but the cause of AD remains unknown. Individuals with AD seem to have a higher incidence of glaucoma and age-related macular degeneration, indicating that similar pathogenesis may underlie these neurodegenerative diseases of the eye and brain. (See Giasson et al., *Free Radic. Biol. Med.* 32:1264-75 (2002); Johnson et al., *Proc. Natl. Acad. Sci. USA* 99:11830-35 (2002); Dentchev et al., *Mol. Vis.* 9:184-90 (2003)).
- [0011] Neuronal cell death underlies the pathology of these diseases. Unfortunately, very few compositions and methods that enhance retinal neuronal cell survival, particularly photoreceptor cell survival, have been discovered. A need therefore exists to identify and develop compositions that that can be used for treatment and prophylaxis of a number of retinal diseases and disorders that have neuronal cell death as a primary, or associated, element in their pathogenesis.
- [0012] In vertebrate photoreceptor cells, the irradiance of a photon causes isomerization of 11-*cis*-retinylidene chromophore to all-*trans*-retinylidene and uncoupling from the visual opsin receptors. This photoisomerization triggers conformational changes of opsins, which, in turn, initiate the biochemical chain of reactions termed phototransduction (Filipek et al., *Annu. Rev. Physiol.* 65:851-79 (2003)). Regeneration of the visual pigments requires that the chromophore be converted back to the 11-*cis*-configuration in the processes collectively called the retinoid (visual) cycle (see, e.g., McBee et al., *Prog. Retin. Eye Res.* 20:469-52 (2001)). First, the chromophore is released from the opsin and reduced in the photoreceptor by retinol dehydrogenases. The product, all-*trans*-retinol, is trapped in the adjacent retinal pigment epithelium (RPE) in the form of insoluble fatty acid esters in subcellular structures known as retinosomes (Imanishi et al., *J. Cell Biol.* 164:373-87 (2004)).
- [0013] In Stargardt's disease (Allikmets et al., *Nat. Genet.* 15:236-46 (1997)), a disease associated with mutations

in the ABCR transporter that acts as a flippase, the accumulation of all-*trans*-retinal may be responsible for the formation of a lipofuscin pigment, A2E, which is toxic towards retinal pigment epithelial cells and causes progressive retinal degeneration and, consequently, loss of vision (Mata et al., *Proc. Natl. Acad. Sci. USA* 97:7154-59 (2000); Weng et al., *Cell* 98:13-23 (1999)). Treating patients with an inhibitor of retinol dehydrogenases, 13-*cis*-RA (Isotretinoin, Accutane®, Roche), has been considered as a therapy that might prevent or slow the formation of A2E and might have protective properties to maintain normal vision (Radu et al., *Proc. Natl. Acad. Sci. USA* 100:4742-47 (2003)). 13-*cis*-RA has been used to slow the synthesis of 11-*cis*-retinal by inhibiting 11-*cis*-RDH (Law et al., *Biochem. Biophys. Res. Commun.* 161:825-9 (1989)), but its use can also be associated with significant night blindness. Others have proposed that 13-*cis*-RA works to prevent chromophore regeneration by binding RPE65, a protein essential for the isomerization process in the eye (Gollapalli et al., *Proc. Natl. Acad. Sci. USA* 101:10030-35 (2004)). Gollapalli et al. reported that 13-*cis*-RA blocked the formation of A2E and suggested that this treatment may inhibit lipofuscin accumulation and, thus, delay either the onset of visual loss in Stargardt's disease or age-related macular degeneration, which are both associated with retinal pigment-associated lipofuscin accumulation. However, blocking the retinoid cycle and forming unliganded opsin may result in more severe consequences and worsening of the patient's prognosis (see, e.g., Van Hooser et al., *J. Biol. Chem.* 277:19173-82 (2002); Woodruff et al., *Nat. Genet.* 35:158-164 (2003)). Failure of the chromophore to form may lead to progressive retinal degeneration and may produce a phenotype similar to Leber Congenital Amaurosis (LCA), is a very rare genetic condition affecting children shortly after birth.

These terms refers to an approach for obtaining beneficial or desired results including but not limited to therapeutic benefit and/or a prophylactic benefit. By therapeutic benefit is meant eradication or amelioration of the underlying disorder being treated. Also, a therapeutic benefit is achieved with the eradication or amelioration of one or more of the physiological symptoms associated with the underlying disorder such that an improvement is observed in the patient, notwithstanding that the patient may still be afflicted with the underlying disorder. For prophylactic benefit, the compositions may be administered to a patient at risk of developing a particular disease, or to a patient reporting one or more of the physiological symptoms of a disease, even though a diagnosis of this disease may not have been made.
- [00241] "Prodrug" is meant to indicate a compound that may be converted under physiological conditions or by solvolysis to a biologically active compound described herein. Thus, the term "prodrug" refers to a precursor of a biologically active compound that is pharmaceutically acceptable. A prodrug may be inactive when administered to a subject, but is converted *in vivo* to an active compound, for example, by hydrolysis. - [00247] Generally speaking, compounds disclosed herein can be prepared in a stepwise manner involving an acetylene formation and a side chain formation of a phenyl ring. Typically, the acetylene formation can take place by attaching an acetylene precursor to a phenyl. For example, in certain embodiments, an acetylene intermediate can be first constructed, which forms the precursor to the alkynyl phenyl core structure. A side chain moiety, which is a precursor to the linkage (*i.e.*, propylene or ethylene oxide) and the nitrogen-containing moiety of the compounds disclosed herein, can then be attached to the acetylene intermediate.
- [00248] In other embodiments, the compounds disclosed herein can be prepared by first preparing a phenyl intermediate having an appropriate side chain, followed by an acetylene formation to provide the alkynyl core structure.
- [00249] The following Methods illustrate various synthetic pathways for preparing acetylene intermediates and the side chain moieties. One skilled in the art will recognize that a method for acetylene formation can be combined with a method for side chain formation to provide the compounds disclosed herein. For example, any one of Methods A-D can be combined with any of Methods E-H, or any of Methods I-J. They can be further combined with any of Methods K-S to modify the linkage and/or the terminal nitrogen-containing moiety.

1. Acetylene Formation:

- [00250] Methods A-D below describe various approaches to acetylene formation.
- [00251] More specifically, Method A illustrates the construction of an acetylene intermediate (A-3) in a Sonogashira or Castro-Stephens reaction. Depending on the sequence of the reactions, Ar can be a phenyl derivative compound that is already attached to a side chain moiety, or Ar may comprise a reactive group (appropriately protected), which will be coupled to a side chain moiety after the acetylene formation step.
- [00252] According to Method A, an alkyne (A-1) can be coupled to an aryl halide or a reactive equivalent (A-2) to provide the acetylene intermediate (A-3) in the presence of a copper (I) catalyst (Castro-Stephens) or a mixture of Pd<sup>0</sup> and Cu<sup>I</sup> catalysts (Sonogashira).
- [00253] The alkyne (A-1) has a terminal acetylene structure that is capable of coupling to A-2. Alkynes comprising diverse R<sub>5</sub> groups can be prepared according to known methods in the art. For example, organic halides (*e.g.*, R<sub>5</sub>Br) can be converted to the corresponding alkyne (A-1) by coupling to an ethyne. The halobenzene or its reactive equivalent (A-2) may be commercially available or can be prepared by known methods in the art.
- [00254] Palladium catalysts suitable for coupling reactions are known to one skilled in the art. Exemplary palladium(0) catalysts include, for example, tetrakis(triphenylphosphine)palladium(0) [Pd(PPh<sub>3</sub>)<sub>4</sub>] and tetrakis(*o*-tolylphosphine)palladium(0), tetrakis(dimethylphenylphosphine)palladium(0), tetrakis(tris-*p*-methoxyphenylphosphine)palladium(0) and the like. It is understood that a palladium (II) salt can also be used, which generates the palladium (0) catalyst *in situ*. Suitable palladium (II) salts include, for example, palladium diacetate [Pd(OAc)<sub>2</sub>], bis(triphenylphosphine)-palladium diacetate and the like.
- [00255] Copper catalysts suitable for coupling reactions are known to one skilled in the art. Typically, the copper

(I) catalyst can be copper (I) iodide.

**Method A**

[00256] Method B shows an alternative construction of the acetylene intermediate (A-3) by coupling an organic halide (*i.e.*, R<sub>5</sub>X) with a phenyl comprising a terminal acetylene (A-5).

**Method B**

[00257] Method C shows the construction of an acetylene intermediate (A-7) through the addition of a terminal acetylene (A-5) to an aldehyde or ketone (A-6).

**Method C**

[00258] Method D shows the construction of an acetylene intermediate (A-8) through the addition of a terminal acetylene (A-5) to an epoxide (A-9).

**Method D**

**2. Side chain formation and modification**

[00259] Methods E-S below describe various approaches to side chain formation and modifications.

[00260] Generally speaking, a suitably substituted phenyl derivative can be coupled to a diverse range of side chains, which may be further modified to provide the final linkages and the nitrogen-containing moieties of the compounds disclosed herein.

[00261] Methods E-H illustrate pathways to form propylene linkages of the compounds disclosed herein.

[00262] Method E illustrates an aryl halide coupled with an allyl alcohol in the presence of a palladium(0) catalyst.

The terminal alcohol group of allyl alcohol has been simultaneously oxidized to an aldehyde group, which can be further reductively aminated to an amine ( $-NR_{12}R_{13}$ ).

**Method E**

[00263] Method F illustrates an aldol condensation between an aryl aldehyde or aryl ketone with a nitrile reagent comprising at least one  $\alpha$ -hydrogen. The resulting condensation intermediate can be further reduced to an amine ( $-NR_{12}R_{13}$ ).

**Method F**

[00264] Method G shows an acylation reaction to form a ketone-based linkage (*i.e.*,  $R_{10}$  and  $R_{11}$  of Formula (I) form an oxo). One skilled in the art will recognize that the  $R'$  group may comprise functional groups that can be further modified.

**Method G**

[00265] Method H shows a ring-opening reaction of an epoxide reagent to form a hydroxy-substituted propylene side chain linkage.

**Method H**

[00266] Method I illustrates an attachment of side chain moieties by an oxygen, which can be a precursor to an ethylene oxide linkage. More specifically, a side chain precursor ( $R'\text{OH}$ ) can be condensed with an aryl derivative by eliminating a molecule of  $\text{H}_2\text{O}$ .  $R'$  may comprise functional groups that can be further modified to prepare linkages and nitrogen-containing moieties of compounds of Formula (III) and its substructures, including Formulae (IIIa) and (IIIb).

[00267] Method J shows a condensation reaction that provides an oxygen linking atom. Here, a molecule of HX is eliminated as the result of the condensation.

[00268] After attachment, the side chain moiety can be further modified to provide the final linkage and the terminal nitrogen-containing moiety for the compounds disclosed herein. The following methods illustrate a variety of synthetic pathways to manipulate or modify the side chain moiety by reduction, oxidation, nucleophilic or electrophilic substitution, fluorination, acylation and the like. As a result, a diverse group of linkages can be synthesized.

[00269] Method K illustrates an amination process in which carboxylic acid is converted to an amine. Typically, the carboxylic acid (or ester) can be first reduced to primary alcohol, which can then be converted to an amine via mesylate, halide, azide, phthalimide, or Mitsunobu reaction and the like. Suitable reducing agents include, for example, sodium borohydride ( $\text{NaBH}_4$ ), sodium cyanoborohydride ( $\text{NaBH}_3\text{CN}$ ), sodium triacetoxyborohydride ( $\text{NaBH}(\text{OCOCH}_3)_3$ ), lithium aluminum hydride ( $\text{LiAlH}_4$ ) and the like. As shown, the resulting amine can be further functionalized, by known methods in the art.

[00270] Additional or alternative modifications can be carried out according to the methods illustrated below.

[00271] Scheme I illustrates a complete synthetic sequence for preparing a compound disclosed herein.

**Scheme I**

[00272] In Scheme I, the side chain moiety is first constructed and the amine protected. The acetylene moiety is then formed through coupling with a terminal acetylene according to Method A. The coupling product is then deprotected to give rise to the final alkynyl phenyl derivative compound comprising a propylene linkage terminating in a primary amine. Other nitrogen-containing moieties ( $-\text{NR}_{12}\text{R}_{13}$ ) can be further derived from the terminal amine, according to known methods in the art.

[00273] One skilled in the art should recognize, however, that the order of the reactions may vary. Thus, in other embodiments, acetylene formation may precede the side chain attachment.

[00274] Scheme II illustrates a complete synthetic sequence for preparing a compound disclosed herein.

[00275] In addition to the generic reaction schemes and methods discussed above, other exemplary reaction schemes are also provided to illustrate methods for preparing any of the compounds disclosed herein.

#### IV. Treatment of Ophthalmic Diseases and Disorders

[00276] Alkynyl phenyl-linked amine derivative compounds as described in detail herein, including compounds having the structure as set forth in any one of Formulae (A)-(G) and (I)-(III), and substructures thereof, and the specific alkynyl phenyl-linked amine compounds described herein that may be useful for treating an ophthalmic disease or disorder may inhibit one or more steps in the visual cycle, for example, by inhibiting or blocking a functional activity of a visual cycle *trans-cis* isomerase (also including a visual cycle *trans-cis* isomerase). The compounds described herein, may inhibit, block, or in some manner interfere with the isomerization step in the visual cycle. In a particular embodiment, the compound inhibits isomerization of an all-*trans*-retinyl ester; in certain embodiments, the all-*trans*-retinyl ester is a fatty acid ester of all-*trans*-retinol, and the compound inhibits isomerization of all-*trans*-retinol to 11-*cis*-retinol. The compound may

bind to, or in some manner interact with, and inhibit the isomerase activity of at least one visual cycle isomerase, which may also be referred to herein and in the art as a retinal isomerase or an isomerohydrolase. The compound may block or inhibit binding of an all-*trans*-retinyl ester substrate to an isomerase. Alternatively, or in addition, the compound may bind to the catalytic site or region of the isomerase, thereby inhibiting the capability of the enzyme to catalyze isomerization of an all-*trans*-retinyl ester substrate. On the basis of scientific data to date, an at least one isomerase that catalyzes the isomerization of all-*trans*-retinyl esters is believed to be located in the cytoplasm of RPE cells. As discussed herein, each step, enzyme, substrate, intermediate, and product of the visual cycle is not yet elucidated (see, e.g., Moiseyev et al., *Proc. Natl. Acad. Sci. USA* 102:12413-18 (2004); Chen et al., *Invest. Ophthalmol. Vis. Sci.* 47:1177-84 (2006); Lamb et al. *supra*).

[00277] A method for determining the effect of a compound on isomerase activity may be performed in vitro as described herein and in the art (Stecher et al., *J Biol Chem* 274:8577-85 (1999); see also Golczak et al., *Proc. Natl. Acad. Sci. USA* 102:8162-67 (2005)). Retinal pigment epithelium (RPE) microsome membranes isolated from an animal (such as bovine, porcine, human, for example) may serve as the source of the isomerase. The capability of the alkynyl phenyl-linked amine derivative compounds to inhibit isomerase may also be determined by an in vivo murine isomerase assay. Brief exposure of the eye to intense light ("photobleaching" of the visual pigment or simply "bleaching") is known to photo-isomerize almost all 11-*cis*-retinal in the retina. The recovery of 11-*cis*-retinal after bleaching can be used to estimate the activity of isomerase *in vivo* (see, e.g., Maeda et al., *J. Neurochem* 85:944-956 (2003); Van Hooser et al., *J Biol Chem* 277:19173-82, 2002). Electroretinographic (ERG) recording may be performed as previously described (Haeseleer et al., *Nat. Neurosci.* 7:1079-87 (2004); Sugitomo et al., *J. Toxicol. Sci.* 22 Suppl 2:315-25 (1997); Keating et al., *Documenta Ophthalmologica* 100:77-92 (2000)). See also Deigner et al., *Science*, 244: 968-971 (1989); Gollapalli et al., *Biochim Biophys Acta.* 1651: 93-101 (2003); Parish, et al., *Proc. Natl. Acad. Sci. USA* 95:14609-13 (1998); Radu, et al., *Proc Natl Acad Sci USA* 101: 5928-33 (2004)). In certain embodiments, compounds that are useful for treating a subject who has or who is at risk of developing any one of the ophthalmic and retinal diseases or disorders described herein have IC<sub>50</sub> levels (compound concentration at which 50% of isomerase activity is inhibited) as measured in the isomerase assays described herein or known in the art that is less than about 1  $\mu$ M; in other embodiments, the determined IC<sub>50</sub> level is less than about 10 nM; in other embodiments, the determined IC<sub>50</sub> level is less than about 50 nM; in certain other embodiments, the determined IC<sub>50</sub> level is less than about 100 nM; in other certain embodiments, the determined IC<sub>50</sub> level is less than about 10  $\mu$ M; in other embodiments, the determined IC<sub>50</sub> level is less than about 50  $\mu$ M; in other certain embodiments, the determined IC<sub>50</sub> level is less than about 100  $\mu$ M or about 500  $\mu$ M; in other embodiments, the determined IC<sub>50</sub> level is between about 1  $\mu$ M and 10  $\mu$ M; in other embodiments, the determined IC<sub>50</sub> level is between about 1 nM and 10 nM. When administered into a subject, one or more compounds of the present invention exhibits an ED<sub>50</sub> value of about 5 mg/kg, 5 mg/kg or less as ascertained by inhibition of an isomerase reaction that results in production of 11-*cis* retinol. In some embodiments, the compounds of the present invention have ED<sub>50</sub> values of about 1 mg/kg when administered into a subject. In other embodiments, the compounds of the present invention have ED<sub>50</sub> values of about 0.1 mg/kg when administered into a subject. The ED<sub>50</sub> values can be measured after about 2 hours, 4 hours, 6 hours, 8 hours or longer upon administering a subject compound or a pharmaceutical composition thereof.

[00278] The compounds described herein may be useful for treating a subject who has an ophthalmic disease or

disorder, particularly a retinal disease or disorder such as age-related macular degeneration or Stargardt's macular dystrophy. In one embodiment, the compounds described herein may inhibit (*i.e.*, prevent, reduce, slow, abrogate, or minimize) accumulation of lipofuscin pigments and lipofuscin-related and/or associated molecules in the eye. In another embodiment, the compounds may inhibit (*i.e.*, prevent, reduce, slow, abrogate, or minimize) *N*-retinylidene-*N*-retinylethanolamine (A2E) accumulation in the eye. The ophthalmic disease may result, at least in part, from lipofuscin pigments accumulation and/or from accumulation of A2E in the eye. Accordingly, in certain embodiments, methods are provided for inhibiting or preventing accumulation of lipofuscin pigments and/or A2E in the eye of a subject. These methods comprise administering to the subject a composition comprising a pharmaceutically acceptable or suitable excipient (*i.e.*, pharmaceutically acceptable or suitable carrier) and an alkynyl phenyl-linked amine derivative compound as described in detail herein, including a compound having the structure as set forth in any one of Formulae (A)-(G) and (I)-(III), and substructures thereof, and the specific alkynyl phenyl-linked amine compounds described herein.

- [00279] Accumulation of lipofuscin pigments in retinal pigment epithelium (RPE) cells has been linked to progression of retinal diseases that result in blindness, including age-related macular degeneration (De Laey et al., *Retina* 15:399-406 (1995)). Lipofuscin granules are autofluorescent lysosomal residual bodies (also called age pigments). The major fluorescent species of lipofuscin is A2E (an orange-emitting fluorophore), which is a positively charged Schiff-base condensation-product formed by *all-trans* retinaldehyde with phosphatidylethanolamine (2:1 ratio) (*see, e.g.*, Eldred et al., *Nature* 361:724-6 (1993); *see also*, Sparrow, *Proc. Natl. Acad. Sci. USA* 100:4353-54 (2003)). Much of the indigestible lipofuscin pigment is believed to originate in photoreceptor cells; deposition in the RPE occurs because the RPE internalize membranous debris that is discarded daily by the photoreceptor cells. Formation of this compound is not believed to occur by catalysis by any enzyme, but rather A2E forms by a spontaneous cyclization reaction. In addition, A2E has a pyridinium bisretinoid structure that once formed may not be enzymatically degraded. Lipofuscin, and thus A2E, accumulate with aging of the human eye and also accumulate in a juvenile form of macular degeneration called Stargardt's disease, and in several other congenital retinal dystrophies.
- [00280] A2E may induce damage to the retina via several different mechanisms. At low concentrations, A2E inhibits normal proteolysis in lysosomes (Holz et al., *Invest. Ophthalmol. Vis. Sci.* 40:737-43 (1999)). At higher, sufficient concentrations, A2E may act as a positively charged lysosomotropic detergent, dissolving cellular membranes, and may alter lysosomal function, release proapoptotic proteins from mitochondria, and ultimately kill the RPE cell (*see, e.g.*, Eldred et al., *supra*; Sparrow et al., *Invest. Ophthalmol. Vis. Sci.* 40:2988-95 (1999); Holz et al., *supra*; Finneman et al., *Proc. Natl. Acad. Sci. USA* 99:3842-347 (2002); Suter et al., *J. Biol. Chem.* 275:39625-30 (2000)). A2E is phototoxic and initiates blue light-induced apoptosis in RPE cells (*see, e.g.*, Sparrow et al., *Invest. Ophthalmol. Vis. Sci.* 43:1222-27 (2002)). Upon exposure to blue light, photooxidative products of A2E are formed (*e.g.*, epoxides) that damage cellular macromolecules, including DNA (Sparrow et al., *J. Biol. Chem.* 278(20):18207-13 (2003)). A2E self-generates singlet oxygen that reacts with A2E to generate epoxides at carbon-carbon double bonds (Sparrow et al., *supra*). Generation of oxygen reactive species upon photoexcitation of A2E causes oxidative damage to the cell, often resulting in cell death. An indirect method of blocking formation of A2E by inhibiting biosynthesis of the direct precursor of A2E, *all-trans*-retinal, has been described (*see* U.S. Patent Application Publication No. 2003/0032078). However, the usefulness of the method described

therein is limited because generation of *all-trans* retinal is an important component of the visual cycle. Other therapies described include neutralizing damage caused by oxidative radical species by using superoxide-dismutase mimetics (*see, e.g.*, U.S. Patent Application Publication No. 2004/0116403) and inhibiting A2E-induced cytochrome C oxidase in retinal cells with negatively charged phospholipids (*see, e.g.*, U.S. Patent Application Publication No. 2003/0050283).

- [00281] The alkynyl phenyl-linked amine derivative compounds described herein may be useful for preventing, reducing, inhibiting, or decreasing accumulation (*i.e.*, deposition) of A2E and A2E-related and/or derived molecules in the RPE. Without wishing to be bound by theory, because the RPE is critical for the maintenance of the integrity of photoreceptor cells, preventing, reducing, or inhibiting damage to the RPE may inhibit degeneration (*i.e.*, enhance the survival or increase or prolong cell viability) of retinal neuronal cells, particularly, photoreceptor cells. Compounds that bind specifically to or interact with A2E A2E-related and/or derived molecules or that affect A2E formation or accumulation may also reduce, inhibit, prevent, or decrease one or more toxic effects of A2E or of A2E-related and/or derived molecules that result in retinal neuronal cell (including a photoreceptor cell) damage, loss, or neurodegeneration, or in some manner decrease retinal neuronal cell viability. Such toxic effects include induction of apoptosis, self-generation of singlet oxygen and generation of oxygen reactive species; self-generation of singlet oxygen to form A2E-epoxides that induce DNA lesions, thus damaging cellular DNA and inducing cellular damage; dissolving cellular membranes; altering lysosomal function; and effecting release of proapoptotic proteins from mitochondria.
- [00282] In other embodiments, the compounds described herein may be used for treating other ophthalmic diseases or disorders, for example, glaucoma, cone-rod dystrophy, retinal detachment, hemorrhagic or hypertensive retinopathy, retinitis pigmentosa, optic neuropathy, inflammatory retinal disease, proliferative vitreoretinopathy, genetic retinal dystrophies, traumatic injury to the optic nerve (such as by physical injury, excessive light exposure, or laser light), hereditary optic neuropathy, neuropathy due to a toxic agent or caused by adverse drug reactions or vitamin deficiency, Sorsby's fundus dystrophy, uveitis, a retinal disorder associated with Alzheimer's disease, a retinal disorder associated with multiple sclerosis; a retinal disorder associated with viral infection (cytomegalovirus or herpes simplex virus), a retinal disorder associated with Parkinson's disease, a retinal disorder associated with AIDS, or other forms of progressive retinal atrophy or degeneration. In another specific embodiment, the disease or disorder results from mechanical injury, chemical or drug-induced injury, thermal injury, radiation injury, light injury, laser injury. The subject compounds are useful for treating both hereditary and non-hereditary retinal dystrophy. These methods are also useful for preventing ophthalmic injury from environmental factors such as light-induced oxidative retinal damage, laser-induced retinal damage, "flash bomb injury," or "light dazzle", refractive errors including but not limited to myopia (*see, e.g.*, Quinn GE et al. *Nature* 1999;399:113-114; Zadnik K et al. *Nature* 2000;404:143-144; Gwiazda J et al. *Nature* 2000;404: 144), etc.
- [00283] In other embodiments, methods are provided herein for inhibiting neovascularization (including but not limited to neovascular glycoma) in the retina using any one or more of the alkynyl phenyl-linked amine derivative compound as described in detail herein, including a compound having the structure as set forth in any one of Formulae (A)-(G) and (I)-(III), and substructures thereof, and the specific alkynyl phenyl-linked amine compounds described herein. In certain other embodiments, methods are provided for reducing hypoxia in the retina using the compounds described herein. These methods comprise administering to a subject, in need thereof, a composition comprising a pharmaceutically acceptable or suitable excipient (*i.e.*,

pharmaceutically acceptable or suitable carrier) and a alkynyl phenyl-linked amine derivative compound as described in detail herein, including a compound having the structure as set forth in any one of Formulae (A)-(G) and (I)-(III), and substructures thereof, and the specific alkynyl phenyl-linked amine compounds described herein.

- [00284] Merely by way of explanation and without being bound by any theory, and as discussed in further detail herein, dark-adapted rod photoreceptors engender a very high metabolic demand (*i.e.*, expenditure of energy (ATP consumption) and consumption of oxygen). The resultant hypoxia may cause and/or exacerbate retinal degeneration, which is likely exaggerated under conditions in which the retinal vasculature is already compromised, including, but not limited to, such conditions as diabetic retinopathy, macular edema, diabetic maculopathy, retinal blood vessel occlusion (which includes retinal venous occlusion and retinal arterial occlusion), retinopathy of prematurity, ischemia reperfusion related retinal injury, as well as in the wet form of age-related macular degeneration (AMD). Furthermore, retinal degeneration and hypoxia may lead to neovascularization, which in turn may worsen the extent of retinal degeneration. The alkynyl phenyl derivative compounds described herein that modulate the visual cycle can be administered to prevent, inhibit, and/or delay dark adaptation of rod photoreceptor cells, and may therefore reduce metabolic demand, thereby reducing hypoxia and inhibiting neovascularization.
- [00285] By way of background, oxygen is a critical molecule for preservation of retinal function in mammals, and retinal hypoxia may be a factor in many retinal diseases and disorders that have ischemia as a component. In most mammals (including humans) with dual vascular supply to the retina, oxygenation of the inner retina is achieved through the intraretinal microvasculature, which is sparse compared to the choriocapillaris that supplies oxygen to the RPE and photoreceptors. The different vascular supply networks create an uneven oxygen tension across the thickness of the retina (Crigle et al., *Invest. Ophthalmol. Vis. Sci.* 43:1922-27 (2002)). Oxygen fluctuation across the retinal layers is related to both the differing capillary densities and disparity in oxygen consumption by various retinal neurons and glia.
- [00286] Local oxygen tension can significantly affect the retina and its microvasculature by regulation of an array of vasoactive agents, including, for example, vascular endothelial growth factor (VEGF). (*See, e.g.*, Werdich et al., *Exp. Eye Res.* 79:623 (2004); Arden et al., *Br. J. Ophthalmol.* 89:764 (2005)). Rod photoreceptors are believed to have the highest metabolic rate of any cell in the body (*see, e.g.*, Arden et al., *supra*). During dark adaptation, the rod photoreceptors recover their high cytoplasmic calcium levels via cGMP-gated calcium channels with concomitant extrusion of sodium ions and water. The efflux of sodium from the cell is an ATP-dependent process, such that the retinal neurons consume up to an estimated five times more oxygen under scotopic (*i.e.*, dark adapted), compared with photopic (*i.e.*, light adapted) conditions. Thus, during characteristic dark adaptation of photoreceptors, the high metabolic demand leads to significant local reduction of oxygen levels in the dark-adapted retina (Ahmed et al, *Invest. Ophthalmol. Vis. Sci.* 34:516 (1993)).
- [00287] Without being bound by any one theory, retinal hypoxia may be further increased in the retina of subjects who have diseases or conditions such as, for example, central retinal vein occlusion in which the retinal vasculature is already compromised. Increasing hypoxia may increase susceptibility to sight-threatening, retinal neovascularization. Neovascularization is the formation of new, functional microvascular networks with red blood cell perfusion, and is a characteristic of retinal degenerative disorders, including, but not limited to, diabetic retinopathy, retinopathy of prematurity, wet AMD and central retinal vein occlusions. Preventing or inhibiting dark adaptation of rod photoreceptor cells, thereby decreasing expenditure of

energy and consumption of oxygen (*i.e.*, reducing metabolic demand), may inhibit or slow retinal degeneration, and/or may promote regeneration of retinal cells, including rod photoreceptor cells and retinal pigment epithelial (RPE) cells, and may reduce hypoxia and may inhibit neovascularization.

- [00288] Methods are described herein for inhibiting (*i.e.*, reducing, preventing, slowing or retarding, in a biologically or statistically significant manner) degeneration of retinal cells (including retinal neuronal cells as described herein and RPE cells) and/or for reducing (*i.e.*, preventing or slowing, inhibiting, abrogating in a biologically or statistically significant manner) retinal ischemia. Methods are also provided for inhibiting (*i.e.*, reducing, preventing, slowing or retarding, in a biologically or statistically significant manner) neovascularization in the eye, particularly in the retina. Such methods comprise contacting the retina, and thus, contacting retinal cells (including retinal neuronal cells such as rod photoreceptor cells, and RPE cells) with at least one of the alkynyl phenyl-linked amine derivative compounds described herein that inhibits at least one visual cycle *trans-cis* isomerase (which may include inhibition of isomerization of an all-*trans*-retinyl ester), under conditions and at a time that may prevent, inhibit, or delay dark adaptation of a rod photoreceptor cell in the retina. As described in further detail herein, in particular embodiments, the compound that contacts the retina interacts with an isomerase enzyme or enzymatic complex in a RPE cell in the retina and inhibits, blocks, or in some manner interferes with the catalytic activity of the isomerase. Thus, isomerization of an all-*trans*-retinyl ester is inhibited or reduced. The at least one alkynyl phenyl-linked derivative compound (or composition comprising at least one compound) may be administered to a subject who has developed and manifested an ophthalmic disease or disorder or who is at risk of developing an ophthalmic disease or disorder, or to a subject who presents or who is at risk of presenting a condition such as retinal neovascularization or retinal ischemia.
- [00289] By way of background, the visual cycle (also called retinoid cycle) refers to the series of enzyme and light-mediated conversions between the 11-*cis* and all-*trans* forms of retinol/retinal that occur in the photoreceptor and retinal pigment epithelial (RPE) cells of the eye. In vertebrate photoreceptor cells, a photon causes isomerization of the 11-*cis*-retinylidene chromophore to all-*trans*-retinylidene coupled to the visual opsin receptors. This photoisomerization triggers conformational changes of opsins, which, in turn, initiate the biochemical chain of reactions termed phototransduction (Filipek et al., *Annu. Rev. Physiol.* 65 851-79 (2003)). After absorption of light and photoisomerization of 11-*cis*-retinal to all-*trans* retinal, regeneration of the visual chromophore is a critical step in restoring photoreceptors to their dark-adapted state. Regeneration of the visual pigment requires that the chromophore be converted back to the 11-*cis*-configuration (reviewed in McBee et al., *Prog. Retin. Eye Res.* 20:469-52 (2001)). The chromophore is released from the opsin and reduced in the photoreceptor by retinol dehydrogenases. The product, all-*trans*-retinol, is trapped in the adjacent retinal pigment epithelium (RPE) in the form of insoluble fatty acid esters in subcellular structures known as retinosomes (Imanishi et al., *J. Cell Biol.* 164:373-78 (2004)).
- [00290] During the visual cycle in rod receptor cells, the 11-*cis* retinal chromophore within the visual pigment molecule, which is called rhodopsin, absorbs a photon of light and is isomerized to the all-*trans* configuration, thereby activating the phototransduction cascade. Rhodopsin is a G-protein coupled receptor (GPCR) that consists of seven membrane-spanning helices that are interconnected by extracellular and cytoplasmic loops. When the all-*trans* form of the retinoid is still covalently bound to the pigment molecule, the pigment is referred to as metarhodopsin, which exists in different forms (*e.g.*, metarhodopsin I and metarhodopsin II). The all-*trans* retinoid is then hydrolyzed and the visual pigment is in the form of the apoprotein, opsin, which is also called apo-rhodopsin in the art and herein. This all-*trans* retinoid is

transported or chaperoned out of the photoreceptor cell and across the extracellular space to the RPE cells, where the retinoid is converted to the 11-*cis* isomer. The movement of the retinoids between the RPE and photoreceptors cells is believed to be accomplished by different chaperone polypeptides in each of the cell types. See Lamb et al., *Progress in Retinal and Eye Research* 23:307-80 (2004).

- [00291] Under light conditions, rhodopsin continually transitions through the three forms, rhodopsin, metarhodopsin, and apo-rhodopsin. When most of the visual pigment is in the rhodopsin form (*i.e.*, bound with 11-*cis* retinal), the rod photoreceptor cell is in a “dark-adapted” state. When the visual pigment is predominantly in the metarhodopsin form (*i.e.*, bound with all-*trans*-retinal), the state of the photoreceptor cell is referred to as a “light-adapted,” and when the visual pigment is apo-rhodopsin (or opsin) and no longer has bound chromophore, the state of the photoreceptor cell is referred to as “rhodopsin-depleted.” Each of the three states of the photoreceptor cell has different energy requirements, and differing levels of ATP and oxygen are consumed. In the dark-adapted state, rhodopsin has no regulatory effect on cation channels, which are open, resulting in an influx of cations ( $\text{Na}^+ / \text{K}^+$  and  $\text{Ca}^{2+}$ ). To maintain the proper level of these cations in the cell during the dark state, the photoreceptor cells actively transport the cations out of the cell via ATP-dependent pumps. Thus maintenance of this “dark current” requires a large amount of energy, resulting in high metabolic demand. In the light-adapted state, metarhodopsin triggers an enzymatic cascade process that results in hydrolysis of GMP, which in turn, closes cation-specific channels in the photoreceptor cell membrane. In the rhodopsin-depleted state, the chromophore is hydrolyzed from metarhodopsin to form the apoprotein, opsin (apo-rhodopsin), which partially regulates the cation channels such that the rod photoreceptor cells exhibit an attenuated current compared with the photoreceptor in the dark-adapted state, resulting in a moderate metabolic demand.
- [00292] Under normal light conditions, the incidence of rod photoreceptors in the dark adapted state is small, in general, 2% or less, and the cells are primarily in the light-adapted or rhodopsin-depleted states, which overall results in a relatively low metabolic demand compared with cells in the dark-adapted state. At night, however, the relative incidence of the dark-adapted photoreceptor state increases profoundly, due to the absence of light adaptation and to the continued operation of the “dark” visual cycle in RPE cells, which replenishes the rod photoreceptor cells with 11-*cis*-retinal. This shift to dark adaptation of the rod photoreceptor causes an increase in metabolic demand (that is, increased ATP and oxygen consumption), leading ultimately to retinal hypoxia and subsequent initiation of angiogenesis. Most ischaemic insults to the retina therefore occur in the dark, for example, at night during sleep.
- [00293] Without being bound by any theory, therapeutic intervention during the “dark” visual cycle may prevent retinal hypoxia and neovascularization that are caused by high metabolic activity in the dark-adapted rod photoreceptor cell. Merely by way of one example, altering the “dark” visual cycle by administering any one of the compounds described herein, which is an isomerase inhibitor, rhodopsin (*i.e.*, 11-*cis* retinal bound) may be reduced or depleted, preventing or inhibiting dark adaptation of rod photoreceptors. This in turn may reduce retinal metabolic demand, attenuating the nighttime risk of retinal ischemia and neovascularization, and thereby inhibiting or slowing retinal degeneration.
- [00294] In one embodiment, at least one of the compounds described herein (*i.e.*, an alkynyl phenyl-linked amine derivative compound as described in detail herein, including a compound having the structure as set forth in any one of Formulae (A)-(G) and (I)-(III), and substructures thereof, and the specific alkynyl phenyl-linked amine compounds described herein) that, for example, blocks, reduces, inhibits, or in some manner attenuates the catalytic activity of a visual cycle isomerase in a statistically or biologically significant

manner, may prevent, inhibit, or delay dark adaptation of a rod photoreceptor cell, thereby inhibiting (*i.e.*, reducing, abrogating, preventing, slowing the progression of, or decreasing in a statistically or biologically significant manner) degeneration of retinal cells (or enhancing survival of retinal cells) of the retina of an eye. In another embodiment, the alkynyl phenyl-linked amine derivative compounds may prevent or inhibit dark adaptation of a rod photoreceptor cell, thereby reducing ischemia (*i.e.*, decreasing, preventing, inhibiting, slowing the progression of ischemia in a statistically or biologically significant manner). In yet another embodiment, any one of the alkynyl phenyl-linked amine derivative compounds described herein may prevent dark adaptation of a rod photoreceptor cell, thereby inhibiting neovascularization in the retina of an eye. Accordingly, methods are provided herein for inhibiting retinal cell degeneration, for inhibiting neovascularization in the retina of an eye of a subject, and for reducing ischemia in an eye of a subject wherein the methods comprise administering at least one alkynyl phenyl-linked amine derivative compound described herein, under conditions and at a time sufficient to prevent, inhibit, or delay dark adaptation of a rod photoreceptor cell. These methods and compositions are therefore useful for treating an ophthalmic disease or disorder including, but not limited to, diabetic retinopathy, diabetic maculopathy, retinal blood vessel occlusion, retinopathy of prematurity, or ischemia reperfusion related retinal injury.

**[00295]** The alkynyl phenyl-linked amine derivative compounds described herein (*i.e.*, an alkynyl phenyl-linked amine derivative compound as described in detail herein, including a compound having the structure as set forth in any one of Formulae (A)-(G) and (I)-(III), and substructures thereof, and the specific alkynyl phenyl-linked amine compounds described herein) may prevent (*i.e.*, delay, slow, inhibit, or decrease) recovery of the visual pigment chromophore, which may prevent or inhibit or retard the formation of retinals and may increase the level of retinyl esters, which perturbs the visual cycle, inhibiting regeneration of rhodopsin, and which prevents, slows, delays or inhibits dark adaptation of a rod photoreceptor cell. In certain embodiments, when dark adaptation of rod photoreceptor cells is prevented in the presence of the compound, dark adaptation is substantially prevented, and the number or percent of rod photoreceptor cells that are rhodopsin-depleted or light adapted is increased compared with the number or percent of cells that are rhodopsin-depleted or light-adapted in the absence of the agent. Thus, in certain embodiments when dark adaptation of rod photoreceptor cells is prevented (*i.e.*, substantially prevented), only at least 2% of rod photoreceptor cells are dark-adapted, similar to the percent or number of cells that are in a dark-adapted state during normal, light conditions. In other certain embodiments, at least 5-10%, 10-20%, 20-30%, 30-40%, 40-50%, 50-60%, or 60-70% of rod photoreceptor cells are dark-adapted after administration of an agent. In other embodiments, the compound acts to delay dark adaptation, and in the presence of the compound dark adaptation of rod photoreceptor cells may be delayed 30 minutes, one hour, two hours, three hours, or four hours compared to dark adaptation of rod photoreceptors in the absence of the compound. By contrast, when an alkynyl phenyl-linked amine derivative compound is administered such that the compound effectively inhibits isomerization of substrate during light-adapted conditions, the compound is administered in such a manner to minimize the percent of rod photoreceptor cells that are dark-adapted, for example, only 2%, 5%, 10%, 20%, or 25% of rod photoreceptors are dark-adapted (*see e.g.*, U.S. Patent Application Publication No. 2006/0069078; Patent Application No. PCT/US2007/002330).

**[00296]** In the retina in the presence of at least one alkynyl phenyl-linked amine derivative compound, regeneration of rhodopsin in a rod photoreceptor cell may be inhibited or the rate of regeneration may be reduced (*i.e.*, inhibited, reduced, or decreased in a statistically or biologically significant manner), at least in part, by

preventing the formation of retinals, reducing the level of retinals, and/or increasing the level of retinyl esters. To determine the level of regeneration of rhodopsin in a rod photoreceptor cell, the level of regeneration of rhodopsin (which may be called a first level) may be determined prior to permitting contact between the compound and the retina (*i.e.*, prior to administration of the agent). After a time sufficient for the compound and the retina and cells of the retina to interact, (*i.e.*, after administration of the compound), the level of regeneration of rhodopsin (which may be called a second level) may be determined. A decrease in the second level compared with the first level indicates that the compound inhibits regeneration of rhodopsin. The level of rhodopsin generation may be determined after each dose, or after any number of doses, and ongoing throughout the therapeutic regimen to characterize the effect of the agent on regeneration of rhodopsin.

[00297] In certain embodiments, the subject in need of the treatments described herein, may have a disease or disorder that results in or causes impairment of the capability of rod photoreceptors to regenerate rhodopsin in the retina. By way of example, inhibition of rhodopsin regeneration (or reduction of the rate of rhodopsin regeneration) may be symptomatic in patients with diabetes. In addition to determining the level of regeneration of rhodopsin in the subject who has diabetes before and after administration of an alkynyl phenyl-linked amine derivative compound described herein, the effect of the compound may also be characterized by comparing inhibition of rhodopsin regeneration in a first subject (or a first group or plurality of subjects) to whom the compound is administered, to a second subject (or second group or plurality of subjects) who has diabetes but who does not receive the agent.

[00298] In another embodiment, a method is provided for preventing or inhibiting dark adaptation of a rod photoreceptor cell (or a plurality of rod photoreceptor cells) in a retina comprising contacting the retina and at least one of the alkynyl phenyl-linked amine derivative compounds described herein (*i.e.*, a compound as described in detail herein, including a compound having the structure as set forth in any one of Formulae (A)-(G) and (I)-(III), and substructures thereof, and the specific alkynyl phenyl-linked amine compounds described herein), under conditions and at a time sufficient to permit interaction between the agent and an isomerase present in a retinal cell (such as an RPE cell). A first level of 11-*cis*-retinal in a rod photoreceptor cell in the presence of the compound may be determined and compared to a second level of 11-*cis*-retinal in a rod photoreceptor cell in the absence of the compound. Prevention or inhibition of dark adaptation of the rod photoreceptor cell is indicated when the first level of 11-*cis*-retinal is less than the second level of 11-*cis*-retinal.

[00299] Inhibiting regeneration of rhodopsin may also include increasing the level of 11-*cis*-retinyl esters present in the RPE cell in the presence of the compound compared with the level of 11-*cis*-retinyl esters present in the RPE cell in the absence of the compound (*i.e.*, prior to administration of the agent). A two-photon imaging technique may be used to view and analyze retinosome structures in the RPE, which structures are believed to store retinyl esters (*see, e.g.*, Imanishi et al., *J. Cell Biol.* 164:373-83 (2004), Epub 2004 January 26.). A first level of retinyl esters may be determined prior to administration of the compound, and a second level of retinyl esters may be determined after administration of a first dose or any subsequent dose, wherein an increase in the second level compared to the first level indicates that the compound inhibits regeneration of rhodopsin.

[00300] Retinyl esters may be analyzed by gradient HPLC according to methods practiced in the art (*see, for example*, Mata et al., *Neuron* 36:69-80 (2002); Trevino et al. *J. Exp. Biol.* 208:4151-57 (2005)). To measure 11-*cis* and all-*trans* retinals, retinoids may be extracted by a formaldehyde method (*see, e.g.*,

Suzuki et al., *Vis. Res.* 28:1061-70 (1988); Okajima and Pepperberg, *Exp. Eye Res.* 65:331-40 (1997)) or by a hydroxylamine method (*see, e.g.*, Groenendijk et al., *Biochim. Biophys. Acta.* 617:430-38 (1980)) before being analyzed on isocratic HPLC (*see, e.g.*, Trevino et al., *supra*). The retinoids may be monitored spectrophotometrically (*see, e.g.*, Maeda et al., *J. Neurochem.* 85:944-956 (2003); Van Hooser et al., *J. Biol. Chem.* 277:19173-82 (2002)).

- [00301] In another embodiment of the methods described herein for treating an ophthalmic disease or disorder, for inhibiting retinal cell degeneration (or enhancing retinal cell survival), for inhibiting neovascularization, and for reducing ischemia in the retina, preventing or inhibiting dark adaptation of a rod photoreceptor cell in the retina comprises increasing the level of apo-rhodopsin (also called opsin) in the photoreceptor cell. The total level of the visual pigment approximates the sum of rhodopsin and apo-rhodopsin and the total level remains constant. Therefore, preventing, delaying, or inhibiting dark adaptation of the rod photoreceptor cell may alter the ratio of apo-rhodopsin to rhodopsin. In particular embodiments, preventing, delaying, or inhibiting dark adaptation by administering an alkynyl phenyl-linked amine derivative compound described herein may increase the ratio of the level of apo-rhodopsin to the level of rhodopsin compared to the ratio in the absence of the agent (for example, prior to administration of the agent). An increase in the ratio (*i.e.*, a statistically or biologically significant increase) of apo-rhodopsin to rhodopsin indicates that the percent or number of rod photoreceptor cells that are rhodopsin-depleted is increased and that the percent or number of rod photoreceptor cells that are dark-adapted is decreased. The ratio of apo-rhodopsin to rhodopsin may be determined throughout the course of therapy to monitor the effect of the agent.
- [00302] Determining or characterizing the capability of compound to prevent, delay, or inhibit dark adaptation of a rod photoreceptor cell may be determined in animal model studies. The level of rhodopsin and the ratio of apo-rhodopsin to rhodopsin may be determined prior to administration (which may be called a first level or first ratio, respectively) of the agent and then after administration of a first or any subsequent dose of the agent (which may be called a second level or second ratio, respectively) to determine and to demonstrate that the level of apo-rhodopsin is greater than the level of apo-rhodopsin in the retina of animals that did not receive the agent. The level of rhodopsin in rod photoreceptor cells may be performed according to methods practiced in the art and provided herein (*see, e.g.*, Yan et al. *J. Biol. Chem.* 279:48189-96 (2004)).
- [00303] A subject in need of such treatment may be a human or may be a non-human primate or other animal (*i.e.*, veterinary use) who has developed symptoms of an ophthalmic disease or disorder or who is at risk for developing an ophthalmic disease or disorder. Examples of non-human primates and other animals include but are not limited to farm animals, pets, and zoo animals (*e.g.*, horses, cows, buffalo, llamas, goats, rabbits, cats, dogs, chimpanzees, orangutans, gorillas, monkeys, elephants, bears, large cats, etc.).
- [00304] Also provided herein are methods for inhibiting (reducing, slowing, preventing) degeneration and enhancing retinal neuronal cell survival (or prolonging cell viability) comprising administering to a subject a composition comprising a pharmaceutically acceptable carrier and an alkynyl phenyl-linked amine derivative compound described in detail herein, including a compound having any one of the structures set forth in Formulae (A)-(G) and (I)-(III) substructures thereof, and specific alkynyl phenyl-linked amine compounds recited herein. Retinal neuronal cells include photoreceptor cells, bipolar cells, horizontal cells, ganglion cells, and amacrine cells. In another embodiment, methods are provided for enhancing survival or inhibiting degeneration of a mature retinal cell such as a RPE cell or a Müller glial cell. In other embodiments, a method for preventing or inhibiting photoreceptor degeneration in an eye of a subject are

provided. A method that prevents or inhibits photoreceptor degeneration may include a method for restoring photoreceptor function in an eye of a subject. Such methods comprise administering to the subject a composition comprising an alkynyl phenyl-linked amine derivative compound as described herein and a pharmaceutically or acceptable carrier (*i.e.*, excipient or vehicle). More specifically, these methods comprise administering to a subject a pharmaceutically acceptable excipient and an alkynyl phenyl-linked amine derivative compound described herein, including a compound having any one of the structures set forth in Formulae (A)-(G) and (I)-(III) or substructures thereof described herein. Without wishing to be bound by theory, the compounds described herein may inhibit an isomerization step of the retinoid cycle (*i.e.*, visual cycle) and/or may slow chromophore flux in a retinoid cycle in the eye.

- [00305] The ophthalmic disease may result, at least in part, from lipofuscin pigment(s) accumulation and/or from accumulation of *N*-retinylidene-*N*-retinylethanolamine (A2E) in the eye. Accordingly, in certain embodiments, methods are provided for inhibiting or preventing accumulation of lipofuscin pigment(s) and/or A2E in the eye of a subject. These methods comprise administering to the subject a composition comprising a pharmaceutically acceptable carrier and an alkynyl phenyl-linked amine compound as described in detail herein, including a compound having the structure as set forth in any one of Formulae (A)-(G) and (I)-(III) or substructures thereof.
- [00306] An alkynyl phenyl-linked amine compound can be administered to a subject who has an excess of a retinoid in an eye (*e.g.*, an excess of 11-*cis*-retinol or 11-*cis*-retinal), an excess of retinoid waste products or intermediates in the recycling of all-*trans*-retinal, or the like. Methods described herein and practiced in the art may be used to determine whether the level of one or more endogenous retinoids in a subject are altered (increased or decreased in a statistically significant or biologically significant manner) during or after administration of any one of the compounds described herein. Rhodopsin, which is composed of the protein opsin and retinal (a vitamin A form), is located in the membrane of the photoreceptor cell in the retina of the eye and catalyzes the only light-sensitive step in vision. The 11-*cis*-retinal chromophore lies in a pocket of the protein and is isomerized to all-*trans* retinal when light is absorbed. The isomerization of retinal leads to a change of the shape of rhodopsin, which triggers a cascade of reactions that lead to a nerve impulse that is transmitted to the brain by the optic nerve.
- [00307] Methods of determining endogenous retinoid levels in a vertebrate eye, and an excess or deficiency of such retinoids, are disclosed in, for example, U.S. Patent Application Publication No: 2005/0159662 (the disclosure of which is incorporated by reference herein in its entirety). Other methods of determining endogenous retinoid levels in a subject, which is useful for determining whether levels of such retinoids are above the normal range, and include for example, analysis by high pressure liquid chromatography (HPLC) of retinoids in a biological sample from a subject. For example, retinoid levels can be determined in a biological sample that is a blood sample (which includes serum or plasma) from a subject. A biological sample may also include vitreous fluid, aqueous humor, intraocular fluid, subretinal fluid, or tears.
- [00308] For example, a blood sample can be obtained from a subject, and different retinoid compounds and levels of one or more of the retinoid compounds in the sample can be separated and analyzed by normal phase high pressure liquid chromatography (HPLC) (*e.g.*, with a HP1100 HPLC and a Beckman, Ultrasphere-Si, 4.6 mm x 250 mm column using 10% ethyl acetate/90% hexane at a flow rate of 1.4 ml/minute). The retinoids can be detected by, for example, detection at 325 nm using a diode-array detector and HP Chemstation A.03.03 software. An excess in retinoids can be determined, for example, by comparison of the profile of retinoids (*i.e.*, qualitative, *e.g.*, identity of specific compounds, and quantitative, *e.g.*, the level

of each specific compound) in the sample with a sample from a normal subject. Persons skilled in the art who are familiar with such assays and techniques and will readily understand that appropriate controls are included.

- [00309] As used herein, increased or excessive levels of endogenous retinoid, such as 11-*cis*-retinol or 11-*cis*-retinal, refer to levels of endogenous retinoid higher than those found in a healthy eye of a young vertebrate of the same species. Administration of an alkynyl phenyl-linked amine derivative compound and reduce or eliminate the requirement for endogenous retinoid. In certain embodiments, the level of endogenous retinoid may be compared before and after any one or more doses of an alkynyl phenyl-linked amine compound is administered to a subject to determine the effect of the compound on the level of endogenous retinoids in the subject.
- [00310] In another embodiment, the methods described herein for treating an ophthalmic disease or disorder, for inhibiting neovascularization, and for reducing ischemia in the retina comprise administering at least one of the alkynyl phenyl-linked amine compounds described herein, thereby effecting a decrease in metabolic demand, which includes effecting a reduction in ATP consumption and in oxygen consumption in rod photoreceptor cells. As described herein, consumption of ATP and oxygen in a dark-adapted rod photoreceptor cell is greater than in rod photoreceptor cells that are light-adapted or rhodopsin-depleted; thus, use of the compounds in the methods described herein may reduce the consumption of ATP in the rod photoreceptor cells that are prevented, inhibited, or delayed from dark adaptation compared with rod photoreceptor cells that are dark-adapted (such as the cells prior to administration or contact with the compound or cells that are never exposed to the compound).
- [00311] The methods described herein that may prevent or inhibit dark adaptation of a rod photoreceptor cell may therefore reduce hypoxia (*i.e.*, reduce in a statistically or biologically significant manner) in the retina. For example, the level of hypoxia (a first level) may be determined prior to initiation of the treatment regimen, that is, prior to the first dosing of the compound (or a composition, as described herein, comprising the compound). The level of hypoxia (for example, a second level) may be determined after the first dosing, and/or after any second or subsequent dosing to monitor and characterize hypoxia throughout the treatment regimen. A decrease (reduction) in the second (or any subsequent) level of hypoxia compared to the level of hypoxia prior to initial administration indicates that the compound and the treatment regimen prevent dark adaptation of the rod photoreceptor cells and may be used for treating ophthalmic diseases and disorders. Consumption of oxygen, oxygenation of the retina, and/or hypoxia in the retina may be determined using methods practiced in the art. For example, oxygenation of the retina may be determined by measuring the fluorescence of flavoproteins in the retina (*see, e.g.*, U.S. Patent No. 4,569,354). Another exemplary method is retinal oximetry that measures blood oxygen saturation in the large vessels of the retina near the optic disc. Such methods may be used to identify and determine the extent of retinal hypoxia before changes in retinal vessel architecture can be detected.
- [00312] A biological sample may be a blood sample (from which serum or plasma may be prepared), biopsy specimen, body fluids (*e.g.*, vitreous fluid, aqueous humor, intraocular fluid, subretinal fluid, or tears), tissue explant, organ culture, or any other tissue or cell preparation from a subject or a biological source. A sample may further refer to a tissue or cell preparation in which the morphological integrity or physical state has been disrupted, for example, by dissection, dissociation, solubilization, fractionation, homogenization, biochemical or chemical extraction, pulverization, lyophilization, sonication, or any other means for processing a sample derived from a subject or biological source. The subject or biological

source may be a human or non-human animal, a primary cell culture (e.g., a retinal cell culture), or culture adapted cell line, including but not limited to, genetically engineered cell lines that may contain chromosomally integrated or episomal recombinant nucleic acid sequences, immortalized or immortalizable cell lines, somatic cell hybrid cell lines, differentiated or differentiable cell lines, transformed cell lines, and the like. Mature retinal cells, including retinal neuronal cells, RPE cells, and Müller glial cells, may be present in or isolated from a biological sample as described herein. For example, the mature retinal cell may be obtained from a primary or long-term cell culture or may be present in or isolated from a biological sample obtained from a subject (human or non-human animal).

### 3. Retinal Cells

- [00313] The retina is a thin layer of nervous tissue located between the vitreous body and choroid in the eye. Major landmarks in the retina are the fovea, the macula, and the optic disc. The retina is thickest near the posterior sections and becomes thinner near the periphery. The macula is located in the posterior retina and contains the fovea and foveola. The foveola contains the area of maximal cone density and, thus, imparts the highest visual acuity in the retina. The foveola is contained within the fovea, which is contained within the macula.
- [00314] The peripheral portion of the retina increases the field of vision. The peripheral retina extends anterior to the ciliary body and is divided into four regions: the near periphery (most posterior), the mid-periphery, the far periphery, and the ora serrata (most anterior). The ora serrata denotes the termination of the retina.
- [00315] The term neuron (or nerve cell) as understood in the art and used herein denotes a cell that arises from neuroepithelial cell precursors. Mature neurons (i.e., fully differentiated cells) display several specific antigenic markers. Neurons may be classified functionally into three groups: (1) afferent neurons (or sensory neurons) that transmit information into the brain for conscious perception and motor coordination; (2) motor neurons that transmit commands to muscles and glands; and (3) interneurons that are responsible for local circuitry; and (4) projection interneurons that relay information from one region of the brain to another region and therefore have long axons. Interneurons process information within specific subregions of the brain and have relatively shorter axons. A neuron typically has four defined regions: the cell body (or soma); an axon; dendrites; and presynaptic terminals. The dendrites serve as the primary input of information from other neural cells. The axon carries the electrical signals that are initiated in the cell body to other neurons or to effector organs. At the presynaptic terminals, the neuron transmits information to another cell (the postsynaptic cell), which may be another neuron, a muscle cell, or a secretory cell.
- [00316] The retina is composed of several types of neuronal cells. As described herein, the types of retinal neuronal cells that may be cultured in vitro by this method include photoreceptor cells, ganglion cells, and interneurons such as bipolar cells, horizontal cells, and amacrine cells. Photoreceptors are specialized light-reactive neural cells and comprise two major classes, rods and cones. Rods are involved in scotopic or dim light vision, whereas photopic or bright light vision originates in the cones. Many neurodegenerative diseases, such as AMD, that result in blindness affect photoreceptors.
- [00317] Extending from their cell bodies, the photoreceptors have two morphologically distinct regions, the inner and outer segments. The outer segment lies furthest from the photoreceptor cell body and contains disks that convert incoming light energy into electrical impulses (phototransduction). The outer segment is attached to the inner segment with a very small and fragile cilium. The size and shape of the outer segments vary between rods and cones and are dependent upon position within the retina. *See Hogan, "Retina" in Histology of the Human Eye: an Atlas and Text Book* (Hogan et al. (eds). WB Saunders;

Philadelphia, PA (1971)); *Eye and Orbit*, 8<sup>th</sup> Ed., Bron et al., (Chapman and Hall, 1997).

- [00318] Ganglion cells are output neurons that convey information from the retinal interneurons (including horizontal cells, bipolar cells, amacrine cells) to the brain. Bipolar cells are named according to their morphology, and receive input from the photoreceptors, connect with amacrine cells, and send output radially to the ganglion cells. Amacrine cells have processes parallel to the plane of the retina and have typically inhibitory output to ganglion cells. Amacrine cells are often subclassified by neurotransmitter or neuromodulator or peptide (such as calretinin or calbindin) and interact with each other, with bipolar cells, and with photoreceptors. Bipolar cells are retinal interneurons that are named according to their morphology; bipolar cells receive input from the photoreceptors and sent the input to the ganglion cells. Horizontal cells modulate and transform visual information from large numbers of photoreceptors and have horizontal integration (whereas bipolar cells relay information radially through the retina).
- [00319] Other retinal cells that may be present in the retinal cell cultures described herein include glial cells, such as Müller glial cells, and retinal pigment epithelial cells (RPE). Glial cells surround nerve cell bodies and axons. The glial cells do not carry electrical impulses but contribute to maintenance of normal brain function. Müller glia, the predominant type of glial cell within the retina, provide structural support of the retina and are involved in the metabolism of the retina (*e.g.*, contribute to regulation of ionic concentrations, degradation of neurotransmitters, and remove certain metabolites (*see, e.g.*, Kljavin et al., *J. Neurosci.* 11:2985 (1991))). Müller's fibers (also known as sustentacular fibers of retina) are sustentacular neuroglial cells of the retina that run through the thickness of the retina from the internal limiting membrane to the bases of the rods and cones where they form a row of junctional complexes.
- [00320] Retinal pigment epithelial (RPE) cells form the outermost layer of the retina, separated from the blood vessel-enriched choroids by Bruch's membrane. RPE cells are a type of phagocytic epithelial cell, with some functions that are macrophage-like, which lies immediately below the retinal photoreceptors. The dorsal surface of the RPE cell is closely apposed to the ends of the rods, and as discs are shed from the rod outer segment they are internalized and digested by RPE cells. Similar process occurs with the disc of the cones. RPE cells also produce, store, and transport a variety of factors that contribute to the normal function and survival of photoreceptors. Another function of RPE cells is to recycle vitamin A as it moves between photoreceptors and the RPE during light and dark adaptation in the process known as the visual cycle.
- [00321] Described herein is an exemplary long-term in vitro cell culture system permits and promotes the survival in culture of mature retinal cells, including retinal neurons, for at least 2-4 weeks, over 2 months, or for as long as 6 months. The cell culture system may be used for identifying and characterizing the alkynyl phenyl-linked amine derivative compounds that are useful in the methods described herein for treating and/or preventing an ophthalmic disease or disorder or for preventing or inhibiting accumulation in the eye of lipofuscin(s) and/or A2E. Retinal cells are isolated from non-embryonic, non-tumorigenic tissue and have not been immortalized by any method such as, for example, transformation or infection with an oncogenic virus. The cell culture system comprises all the major retinal neuronal cell types (photoreceptors, bipolar cells, horizontal cells, amacrine cells, and ganglion cells), and also may include other mature retinal cells such as retinal pigment epithelial cells and Müller glial cells.
- [00322] For example, a blood sample can be obtained from a subject, and different retinoid compounds and levels of one or more of the retinoid compounds in the sample can be separated and analyzed by normal phase high pressure liquid chromatography (HPLC) (*e.g.*, with a HP1100 HPLC and a Beckman, Ultrasphere-Si,

4.6 mm x 250 mm column using 10% ethyl acetate/90% hexane at a flow rate of 1.4 ml/minute). The retinoids can be detected by, for example, detection at 325 nm using a diode-array detector and HP Chemstation A.03.03 software. An excess in retinoids can be determined, for example, by comparison of the profile of retinoids (*i.e.*, qualitative, *e.g.*, identity of specific compounds, and quantitative, *e.g.*, the level of each specific compound) in the sample with a sample from a normal subject. Persons skilled in the art who are familiar with such assays and techniques and will readily understand that appropriate controls are included.

[00323] As used herein, increased or excessive levels of endogenous retinoid, such as 11-*cis*-retinol or 11-*cis*-retinal, refer to levels of endogenous retinoid higher than those found in a healthy eye of a young vertebrate of the same species. Administration of an alkynyl phenyl-linked amine derivative compound and reduce or eliminate the requirement for endogenous retinoid.

4. In Vivo and In Vitro Methods for Determining Therapeutic Effectiveness of Compounds

[00324] In one embodiment, methods are provided for using the compounds described herein for enhancing or prolonging retinal cell survival, including retinal neuronal cell survival and RPE cell survival. Also provided herein are methods for inhibiting or preventing degeneration of a retinal cell, including a retinal neuronal cell (*e.g.*, a photoreceptor cell, an amacrine cell, a horizontal cell, a bipolar cell, and a ganglion cell) and other mature retinal cells such as retinal pigment epithelial cells and Müller glial cells using the compounds described herein. Such methods comprise, in certain embodiments, administration of an alkynyl phenyl-linked amine derivative compound as described herein. Such a compound is useful for enhancing retinal cell survival, including photoreceptor cell survival and retinal pigment epithelia survival, inhibiting or slowing degeneration of a retinal cell, and thus increasing retinal cell viability, which can result in slowing or halting the progression of an ophthalmic disease or disorder or retinal injury, which are described herein.

[00325] The effect of an alkynyl phenyl-linked amine derivative compound on retinal cell survival (and/or retinal cell degeneration) may be determined by using cell culture models, animal models, and other methods that are described herein and practiced by persons skilled in the art. By way of example, and not limitation, such methods and assays include those described in Oglivie et al., *Exp. Neurol.* 161:675-856 (2000); U.S. Patent No. 6,406,840; WO 01/81551; WO 98/12303; U.S. Patent Application No. 2002/0009713; WO 00/40699; U.S. Patent No. 6,117,675; U.S. Patent No. 5,736,516; WO 99/29279; WO 01/83714; WO 01/42784; U.S. Patent No. 6,183,735; U.S. Patent No. 6,090,624; WO 01/09327; U.S. Patent No. 5,641,750; U.S. Patent Application Publication No. 2004/0147019; and U.S. Patent Application Publication No. 2005/0059148.

[00326] Compounds described herein that may be useful for treating an ophthalmic disease or disorder (including a retinal disease or disorder) may inhibit, block, impair, or in some manner interfere with one or more steps in the visual cycle (also called the retinoid cycle herein and in the art). Without wishing to be bound by a particular theory, an alkynyl phenyl-linked amine derivative may inhibit or block an isomerization step in the visual cycle, for example, by inhibiting or blocking a functional activity of a visual cycle *trans-cis* isomerase. The compounds described herein may inhibit, directly or indirectly, isomerization of all-*trans*-retinol to 11-*cis*-retinol. The compounds may bind to, or in some manner interact with, and inhibit the isomerase activity of at least one isomerase in a retinal cell. Any one of the compounds described herein may also directly or indirectly inhibit or reduce the activity of an isomerase that is involved in the visual cycle. The compound may block or inhibit the capability of the isomerase to bind to one or more

substrates, including but not limited to, an all-*trans*-retinyl ester substrate or all-*trans*-retinol.

Alternatively, or in addition, the compound may bind to the catalytic site or region of the isomerase, thereby inhibiting the capability of the enzyme to catalyze isomerization of at least one substrate. On the basis of scientific data to date, an at least one isomerase that catalyzes the isomerization of a substrate during the visual cycle is believed to be located in the cytoplasm of RPE cells. As discussed herein, each step, enzyme, substrate, intermediate, and product of the visual cycle is not yet elucidated. While a polypeptide called RPE65, which has been found in the cytoplasm and membrane bound in RPE cells, is hypothesized to have isomerase activity (and has also been referred to in the art as having isomerohydrolase activity) (*see, e.g.,* Moiseyev et al., *Proc. Natl. Acad. Sci. USA* 102:12413-18 (2004); Chen et al., *Invest. Ophthalmol. Vis. Sci.* 47:1177-84 (2006)), other persons skilled in the art believe that the RPE65 acts primarily as a chaperone for all-*trans*-retinyl esters (*see, e.g.,* Lamb et al. *supra*).

[00327] Exemplary methods are described herein and practiced by persons skilled in the art for determining the level of enzymatic activity of a visual cycle isomerase in the presence of any one of the compounds described herein. A compound that decreases isomerase activity may be useful for treating an ophthalmic disease or disorder. Thus, methods are provided herein for detecting inhibition of isomerase activity comprising contacting (*i.e.*, mixing, combining, or in some manner permitting the compound and isomerase to interact) a biological sample comprising the isomerase and an alkynyl phenyl-linked amine derivative compound described herein and then determining the level of enzymatic activity of the isomerase. A person having skill in the art will appreciate that as a control, the level of activity of the isomerase in the absence of a compound or in the presence of a compound known not to alter the enzymatic activity of the isomerase can be determined and compared to the level of activity in the presence of the compound. A decrease in the level of isomerase activity in the presence of the compound compared to the level of isomerase activity in the absence of the compound indicates that the compound may be useful for treating an ophthalmic disease or disorder, such as age-related macular degeneration or Stargardt's disease. A decrease in the level of isomerase activity in the presence of the compound compared to the level of isomerase activity in the absence of the compound indicates that the compound may also be useful in the methods described herein for inhibiting or preventing dark adaptation, inhibiting neovascularization and reducing hypoxia and thus useful for treating an ophthalmic disease or disorder, for example, diabetic retinopathy, diabetic maculopathy, retinal blood vessel occlusion, retinopathy of prematurity, or ischemia reperfusion related retinal injury.

[00328] The capability of an alkynyl phenyl-linked amine compound described herein to inhibit or to prevent dark adaptation of a rod photoreceptor cell by inhibiting regeneration of rhodopsin may be determined by in vitro assays and/or in vivo animal models. By way of example, inhibition of regeneration may be determined in a mouse model in which a diabetes-like condition is induced chemically or in a diabetic mouse model (*see, e.g.,* Phipps et al., *Invest. Ophthalmol. Vis. Sci.* 47:3187-94 (2006); Ramsey et al., *Invest. Ophthalmol. Vis. Sci.* 47:5116-24 (2006)). The level of rhodopsin (a first level) may be determined (for example, spectrophotometrically) in the retina of animals prior to administration of the agent and compared with the level (a second level) of rhodopsin measured in the retina of animals after administration of the agent. A decrease in the second level of rhodopsin compared with the first level of rhodopsin indicates that the agent inhibits regeneration of rhodopsin. The appropriate controls and study design to determine whether regeneration of rhodopsin is inhibited in a statistically significant or biologically significant manner can be readily determined and implemented by persons skilled in the art.

- [00329] Methods and techniques for determining or characterizing the effect of any one of the compounds described herein on dark adaptation and rhodopsin regeneration in rod photoreceptor cells in a mammal, including a human, may be performed according to procedures described herein and practiced in the art. For example, detection of a visual stimulus after exposure to light (*i.e.*, photobleaching) versus time in darkness may be determined before administration of the first dose of the compound and at a time after the first dose and/or any subsequent dose. A second method for determining prevention or inhibition of dark adaptation by the rod photoreceptor cells includes measurement of the amplitude of at least one, at least two, at least three, or more electroretinogram components, which include, for example, the a-wave and the b-wave. See, for example, Lamb et al., *supra*; Asi et al., *Documenta Ophthalmologica* 79:125-39 (1992).
- [00330] Inhibiting regeneration of rhodopsin by an alkynyl phenyl-linked amine compound described herein comprises reducing the level of the chromophore, 11-*cis*-retinal, that is produced and present in the RPE cell, and consequently reducing the level of 11-*cis*-retinal that is present in the photoreceptor cell. Thus, the compound, when permitted to contact the retina under suitable conditions and at a time sufficient to prevent dark adaptation of a rod photoreceptor cell and to inhibit regeneration of rhodopsin in the rod photoreceptor cell, effects a reduction in the level of 11-*cis*-retinal in a rod photoreceptor cell (*i.e.*, a statistically significant or biologically significant reduction). That is, the level of 11-*cis* retinal in a rod photoreceptor cell is greater prior to administration of the compound when compared with the level of 11-*cis*-retinal in the photoreceptor cell after the first and/or any subsequent administration of the compound. A first level of 11-*cis*-retinal may be determined prior to administration of the compound, and a second level of 11-*cis*-retinal may be determined after administration of a first dose or any subsequent dose to monitor the effect of the compound. A decrease in the second level compared to the first level indicates that the compound inhibits regeneration of rhodopsin and thus inhibits or prevents dark adaptation of the rod photoreceptor cells.
- [00331] An exemplary method for determining or characterizing the capability of an alkynyl phenyl-linked amine compound to reduce retinal hypoxia includes measuring the level of retinal oxygenation, for example, by Magnetic Resonance Imaging (MRI) to measure changes in oxygen pressure (*see, e.g.*, Luan et al., *Invest. Ophthalmol. Vis. Sci.* 47:320-28 (2006)). Methods are also available and routinely practiced in the art to determine or characterize the capability of compounds described herein to inhibit degeneration of a retinal cell (*see, e.g.*, Wenzel et al., *Prog. Retin. Eye Res.* 24:275-306 (2005)).
- [00332] Animal models may be used to characterize and identify compounds that may be used to treat retinal diseases and disorders. A recently developed animal model may be useful for evaluating treatments for macular degeneration has been described by Ambati et al. (*Nat. Med.* 9:1390-97 (2003); Epub 2003 Oct 19). This animal model is one of only a few exemplary animal models presently available for evaluating a compound or any molecule for use in treating (including preventing) progression or development of a retinal disease or disorder. Animal models in which the *ABCR* gene, which encodes an ATP-binding cassette transporter located in the rims of photoreceptor outer segment discs, may be used to evaluate the effect of a compound. Mutations in the *ABCR* gene are associated with Stargardt's disease, and heterozygous mutations in *ABCR* have been associated with AMD. Accordingly, animals have been generated with partial or total loss of *ABCR* function and may be used to characterize the alkynyl phenyl-linked amine compounds described herein. (*See, e.g.*, Mata et al., *Invest. Ophthalmol. Sci.* 42:1685-90 (2001); Weng et al., *Cell* 98:13-23 (1999); Mata et al., *Proc. Natl. Acad. Sci. USA* 97:7154-49 (2000); US 2003/0032078; U.S. Patent No. 6,713,300). Other animal models include the use of mutant ELOVL4

transgenic mice to determine lipofuscin accumulation, electrophysiology, and photoreceptor degeneration, or prevention or inhibition thereof (*see, e.g., Karan et al., Proc. Natl. Acad. Sci. USA 102:4164-69 (2005)*).

[00333] The effect of any one of the compounds described herein may be determined in a diabetic retinopathy animal model, such as described in Luan et al. or may be determined in a normal animal model, in which the animals have been light or dark adapted in the presence and absence of any one of the compounds described herein. Another exemplary method for determining the capability of the agent to reduce retinal hypoxia measures retinal hypoxia by deposition of a hydroxyprobe (*see, e.g., de Gooyer et al. (Invest. Ophthalmol. Vis. Sci. 47:5553-60 (2006))*). Such a technique may be performed in an animal model using Rho<sup>-</sup>/Rho<sup>-</sup> knockout mice (*see de Gooyer et al., supra*) in which at least one compound described herein is administered to group(s) of animals in the presence and absence of the at least one compound, or may be performed in normal, wildtype animals in which at least one compound described herein is administered to group(s) of animals in the presence and absence of the at least one compound. Other animal models include models for determining photoreceptor function, such as rat models that measure electretinographic (ERG) oscillatory potentials (*see, e.g., Liu et al., Invest. Ophthalmol. Vis. Sci. 47:5447-52 (2006)*; Akula et al., *Invest. Ophthalmol. Vis. Sci. 48:4351-59 (2007)*; Liu et al., *Invest. Ophthalmol. Vis. Sci. 47:2639-47 (2006)*; Dembinska et al., *Invest. Ophthalmol. Vis. Sci. 43:2481-90 (2002)*; Penn et al., *Invest. Ophthalmol. Vis. Sci. 35:3429-35 (1994)*; Hancock et al., *Invest. Ophthalmol. Vis. Sci. 45:1002-1008 (2004)*).

[00334] A method for determining the effect of a compound on isomerase activity may be performed in vitro as described herein and in the art (Stecher et al., *J. Biol. Chem. 274:8577-85 (1999)*; *see also Golczak et al., Proc. Natl. Acad. Sci. USA 102:8162-67 (2005)*). Retinal pigment epithelium (RPE) microsome membranes isolated from an animal (such as bovine, porcine, human, for example) may serve as the source of the isomerase. The capability of the alkynyl phenyl-linked amine derivative compounds to inhibit isomerase may also be determined by an in vivo murine isomerase assay. Brief exposure of the eye to intense light ("photobleaching" of the visual pigment or simply "bleaching") is known to photo-isomerize almost all 11-*cis*-retinal in the retina. The recovery of 11-*cis*-retinal after bleaching can be used to estimate the activity of isomerase *in vivo* (*see, e.g., Maeda et al., J. Neurochem. 85:944-956 (2003)*; Van Hooser et al., *J. Biol. Chem. 277:19173-82, 2002*). Electoretinographic (ERG) recording may be performed as previously described (Haeseleer et al., *Nat. Neurosci. 7:1079-87 (2004)*; Sugitomo et al., *J. Toxicol. Sci. 22 Suppl 2:315-25 (1997)*; Keating et al., *Documenta Ophthalmologica 100:77-92 (2000)*). *See also* Deigner et al., *Science*, 244: 968-971 (1989); Gollapalli et al., *Biochim. Biophys. Acta 1651: 93-101 (2003)*; Parish, et al., *Proc. Natl. Acad. Sci. USA 95:14609-13 (1998)*; Radu et al., *Proc Natl Acad Sci USA 101: 5928-33 (2004)*.

[00335] Cell culture methods, such as the method described herein, are also useful for determining the effect of a compound described herein on retinal neuronal cell survival. Exemplary cell culture models are described herein and described in detail in U.S. Patent Application Publication No. US 2005-0059148 and U.S. Patent Application Publication No. US2004-0147019 (which are incorporated by reference in their entirety), which are useful for determining the capability of an alkynyl phenyl-linked amine derivative compound as described herein to enhance or prolong survival of neuronal cells, particularly retinal neuronal cells, and of retinal pigment epithelial cells, and inhibit, prevent, slow, or retard degeneration of an eye, or the retina or retinal cells thereof, or the RPE, and which compounds are useful for treating ophthalmic diseases and disorders.

[00336] The cell culture model comprises a long-term or extended culture of mature retinal cells, including retinal

neuronal cells (*e.g.*, photoreceptor cells, amacrine cells, ganglion cells, horizontal cells, and bipolar cells). The cell culture system and methods for producing the cell culture system provide extended culture of photoreceptor cells. The cell culture system may also comprise retinal pigment epithelial (RPE) cells and Müller glial cells.

- [00337] The retinal cell culture system may also comprise a cell stressor. The application or the presence of the stressor affects the mature retinal cells, including the retinal neuronal cells, *in vitro*, in a manner that is useful for studying disease pathology that is observed in a retinal disease or disorder. The cell culture model provides an *in vitro* neuronal cell culture system that will be useful in the identification and biological testing of an alkynyl phenyl-linked amine derivative compound that is suitable for treatment of neurological diseases or disorders in general, and for treatment of degenerative diseases of the eye and brain in particular. The ability to maintain primary, *in vitro*-cultured cells from mature retinal tissue, including retinal neurons over an extended period of time in the presence of a stressor enables examination of cell-to-cell interactions, selection and analysis of neuroactive compounds and materials, use of a controlled cell culture system for *in vitro* CNS and ophthalmic tests, and analysis of the effects on single cells from a consistent retinal cell population.
- [00338] The cell culture system and the retinal cell stress model comprise cultured mature retinal cells, retinal neurons, and a retinal cell stressor, which may be used for screening and characterizing an alkynyl phenyl-linked amine derivative compound that are capable of inducing or stimulating the regeneration of CNS tissue that has been damaged by disease. The cell culture system provides a mature retinal cell culture that is a mixture of mature retinal neuronal cells and non-neuronal retinal cells. The cell culture system comprises all the major retinal neuronal cell types (photoreceptors, bipolar cells, horizontal cells, amacrine cells, and ganglion cells), and may also include other mature retinal cells such as RPE and Müller glial cells. By incorporating these different types of cells into the *in vitro* culture system, the system essentially resembles an “artificial organ” that is more akin to the natural *in vivo* state of the retina.
- [00339] Viability of one or more of the mature retinal cell types that are isolated (harvested) from retinal tissue and plated for tissue culture may be maintained for an extended period of time, for example, from two weeks up to six months. Viability of the retinal cells may be determined according to methods described herein and known in the art. Retinal neuronal cells, similar to neuronal cells in general, are not actively dividing cells *in vivo* and thus cell division of retinal neuronal cells would not necessarily be indicative of viability. An advantage of the cell culture system is the ability to culture amacrine cells, photoreceptors, and associated ganglion projection neurons and other mature retinal cells for extended periods of time, thereby providing an opportunity to determine the effectiveness of an alkynyl phenyl-linked amine derivative compound described herein for treatment of retinal disease.
- [00340] The biological source of the retinal cells or retinal tissue may be mammalian (*e.g.*, human, non-human primate, ungulate, rodent, canine, porcine, bovine, or other mammalian source), avian, or from other genera. Retinal cells including retinal neurons from post-natal non-human primates, post-natal pigs, or post-natal chickens may be used, but any adult or post-natal retinal tissue may be suitable for use in this retinal cell culture system.
- [00341] In certain instances, the cell culture system may provide for robust long-term survival of retinal cells without inclusion of cells derived from or isolated or purified from non-retinal tissue. Such a cell culture system comprises cells isolated solely from the retina of the eye and thus is substantially free of types of cells from other parts or regions of the eye that are separate from the retina, such as the ciliary body, iris,

choroid, and vitreous. Other cell culture methods include the addition of non-retinal cells, such as ciliary body cell and/or stem cells (which may or may not be retinal stem cells) and/or additional purified glial cells.

- [00342] The in vitro retinal cell culture systems described herein may serve as physiological retinal models that can be used to characterize aspects of the physiology of the retina. This physiological retinal model may also be used as a broader general neurobiology model. A cell stressor may be included in the model cell culture system. A cell stressor, which as described herein is a retinal cell stressor, adversely affects the viability or reduces the viability of one or more of the different retinal cell types, including types of retinal neuronal cells, in the cell culture system. A person skilled in the art would readily appreciate and understand that as described herein a retinal cell that exhibits reduced viability means that the length of time that a retinal cell survives in the cell culture system is reduced or decreased (decreased lifespan) and/or that the retinal cell exhibits a decrease, inhibition, or adverse effect of a biological or biochemical function (*e.g.*, decreased or abnormal metabolism; initiation of apoptosis; etc.) compared with a retinal cell cultured in an appropriate control cell system (*e.g.*, the cell culture system described herein in the absence of the cell stressor). Reduced viability of a retinal cell may be indicated by cell death; an alteration or change in cell structure or morphology; induction and/or progression of apoptosis; initiation, enhancement, and/or acceleration of retinal neuronal cell neurodegeneration (or neuronal cell injury).
- [00343] Methods and techniques for determining cell viability are described in detail herein and are those with which skilled artisans are familiar. These methods and techniques for determining cell viability may be used for monitoring the health and status of retinal cells in the cell culture system and for determining the capability of the alkynyl phenyl-linked amine derivative compounds described herein to alter (preferably increase, prolong, enhance, improve) retinal cell or retinal pigment epithelial cell viability or retinal cell survival.
- [00344] The addition of a cell stressor to the cell culture system is useful for determining the capability of an alkynyl phenyl-linked amine derivative compound to abrogate, inhibit, eliminate, or lessen the effect of the stressor. The retinal cell culture system may include a cell stressor that is chemical (*e.g.*, A2E, cigarette smoke concentrate); biological (for example, toxin exposure; beta-amyloid; lipopolysaccharides); or non-chemical, such as a physical stressor, environmental stressor, or a mechanical force (*e.g.*, increased pressure or light exposure) (see, *e.g.*, US 2005-0059148).
- [00345] The retinal cell stressor model system may also include a cell stressor such as, but not limited to, a stressor that may be a risk factor in a disease or disorder or that may contribute to the development or progression of a disease or disorder, including but not limited to, light of varying wavelengths and intensities; A2E; cigarette smoke condensate exposure; oxidative stress (*e.g.*, stress related to the presence of or exposure to hydrogen peroxide, nitroprusside,  $Zn^{++}$ , or  $Fe^{++}$ ); increased pressure (*e.g.*, atmospheric pressure or hydrostatic pressure), glutamate or glutamate agonist (*e.g.*, *N*-methyl-D-aspartate (NMDA); alpha-amino-3-hydroxy-5-methylisoxazole-4-propionate (AMPA); kainic acid; quisqualic acid; ibotenic acid; quinolinic acid; aspartate; trans-1-aminocyclopentyl-1,3-dicarboxylate (ACPD)); amino acids (*e.g.*, aspartate, L-cysteine; beta-N-methylamine-L-alanine); heavy metals (such as lead); various toxins (for example, mitochondrial toxins (*e.g.*, malonate, 3-nitropropionic acid; rotenone, cyanide); MPTP (1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine), which metabolizes to its active, toxic metabolite MPP<sup>+</sup> (1-methyl-4-phenylpyridine)); 6-hydroxydopamine; alpha-synuclein; protein kinase C activators (*e.g.*, phorbol myristate acetate); biogenic amino stimulants (for example, methamphetamine, MDMA (3-4

methylenedioxymethamphetamine)); or a combination of one or more stressors. Useful retinal cell stressors include those that mimic a neurodegenerative disease that affects any one or more of the mature retinal cells described herein. A chronic disease model is of particular importance because most neurodegenerative diseases are chronic. Through use of this in vitro cell culture system, the earliest events in long-term disease development processes may be identified because an extended period of time is available for cellular analysis.

- [00346] A retinal cell stressor may alter (*i.e.*, increase or decrease in a statistically significant manner) viability of retinal cells such as by altering survival of retinal cells, including retinal neuronal cells and RPE cells, or by altering neurodegeneration of retinal neuronal cells and/or RPE cells. Preferably, a retinal cell stressor adversely affects a retinal neuronal cell or RPE cell such that survival of a retinal neuronal cell or RPE cell is decreased or adversely affected (*i.e.*, the length of time during which the cells are viable is decreased in the presence of the stressor) or neurodegeneration (or neuron cell injury) of the cell is increased or enhanced. The stressor may affect only a single retinal cell type in the retinal cell culture or the stressor may affect two, three, four, or more of the different cell types. For example, a stressor may alter viability and survival of photoreceptor cells but not affect all the other major cell types (*e.g.*, ganglion cells, amacrine cells, horizontal cells, bipolar cells, RPE, and Müller glia). Stressors may shorten the survival time of a retinal cell (in vivo or in vitro), increase the rapidity or extent of neurodegeneration of a retinal cell, or in some other manner adversely affect the viability, morphology, maturity, or lifespan of the retinal cell.
- [00347] The effect of a cell stressor (in the presence and absence of an alkynyl phenyl-linked amine derivative compound) on the viability of retinal cells in the cell culture system may be determined for one or more of the different retinal cell types. Determination of cell viability may include evaluating structure and/or a function of a retinal cell continually at intervals over a length of time or at a particular time point after the retinal cell culture is prepared. Viability or long term survival of one or more different retinal cell types or one or more different retinal neuronal cell types may be examined according to one or more biochemical or biological parameters that are indicative of reduced viability, such as apoptosis or a decrease in a metabolic function, prior to observation of a morphological or structural alteration.
- [00348] A chemical, biological, or physical cell stressor may reduce viability of one or more of the retinal cell types present in the cell culture system when the stressor is added to the cell culture under conditions described herein for maintaining the long-term cell culture. Alternatively, one or more culture conditions may be adjusted so that the effect of the stressor on the retinal cells can be more readily observed. For example, the concentration or percent of fetal bovine serum may be reduced or eliminated from the cell culture when cells are exposed to a particular cell stressor (*see, e.g.*, US 2005-0059148). Alternatively, retinal cells cultured in media containing serum at a particular concentration for maintenance of the cells may be abruptly exposed to media that does not contain any level of serum.
- [00349] The retinal cell culture may be exposed to a cell stressor for a period of time that is determined to reduce the viability of one or more retinal cell types in the retinal cell culture system. The cells may be exposed to a cell stressor immediately upon plating of the retinal cells after isolation from retinal tissue. Alternatively, the retinal cell culture may be exposed to a stressor after the culture is established, or any time thereafter. When two or more cell stressors are included in the retinal cell culture system, each stressor may be added to the cell culture system concurrently and for the same length of time or may be added separately at different time points for the same length of time or for differing lengths of time during the culturing of the

retinal cell system. An alkynyl phenyl-linked amine compound may be added before the retinal cell culture is exposed to a cell stressor, may be added concurrently with the cell stressor, or may be added after exposure of the retinal cell culture to the stressor.

- [00350] Photoreceptors may be identified using antibodies that specifically bind to photoreceptor-specific proteins such as opsins, peripherins, and the like. Photoreceptors in cell culture may also be identified as a morphologic subset of immunocytochemically labeled cells by using a pan-neuronal marker or may be identified morphologically in enhanced contrast images of live cultures. Outer segments can be detected morphologically as attachments to photoreceptors.
- [00351] Retinal cells including photoreceptors can also be detected by functional analysis. For example, electrophysiology methods and techniques may be used for measuring the response of photoreceptors to light. Photoreceptors exhibit specific kinetics in a graded response to light. Calcium-sensitive dyes may also be used to detect graded responses to light within cultures containing active photoreceptors. For analyzing stress-inducing compounds or potential neurotherapeutics, retinal cell cultures can be processed for immunocytochemistry, and photoreceptors and/or other retinal cells can be counted manually or by computer software using photomicroscopy and imaging techniques. Other immunoassays known in the art (*e.g.*, ELISA, immunoblotting, flow cytometry) may also be useful for identifying and characterizing the retinal cells and retinal neuronal cells of the cell culture model system described herein.
- [00352] The retinal cell culture stress models may also be useful for identification of both direct and indirect pharmacologic agent effects by the bioactive agent of interest, such as an alkynyl phenyl-linked amine derivative compound as described herein. For example, a bioactive agent added to the cell culture system in the presence of one or more retinal cell stressors may stimulate one cell type in a manner that enhances or decreases the survival of other cell types. Cell/cell interactions and cell/extracellular component interactions may be important in understanding mechanisms of disease and drug function. For example, one neuronal cell type may secrete trophic factors that affect growth or survival of another neuronal cell type (*see, e.g.*, WO 99/29279).
- [00353] In another embodiment, an alkynyl phenyl-linked amine derivative compound is incorporated into screening assays comprising the retinal cell culture stress model system described herein to determine whether and/or to what level or degree the compound increases or prolongs viability (*i.e.*, increases in a statistically significant or biologically significant manner) of a plurality of retinal cells. A person skilled in the art would readily appreciate and understand that as described herein a retinal cell that exhibits increased viability means that the length of time that a retinal cell survives in the cell culture system is increased (increased lifespan) and/or that the retinal cell maintains a biological or biochemical function (normal metabolism and organelle function; lack of apoptosis; etc.) compared with a retinal cell cultured in an appropriate control cell system (*e.g.*, the cell culture system described herein in the absence of the compound). Increased viability of a retinal cell may be indicated by delayed cell death or a reduced number of dead or dying cells; maintenance of structure and/or morphology; lack of or delayed initiation of apoptosis; delay, inhibition, slowed progression, and/or abrogation of retinal neuronal cell neurodegeneration or delaying or abrogating or preventing the effects of neuronal cell injury. Methods and techniques for determining viability of a retinal cell and thus whether a retinal cell exhibits increased viability are described in greater detail herein and are known to persons skilled in the art.
- [00354] In certain embodiments, a method is provided for determining whether an alkynyl phenyl-linked amine derivative compound, enhances survival of photoreceptor cells. One method comprises contacting a retinal

cell culture system as described herein with an alkynyl phenyl-linked amine compound under conditions and for a time sufficient to permit interaction between the retinal neuronal cells and the compound. Enhanced survival (prolonged survival) may be measured according to methods described herein and known in the art, including detecting expression of rhodopsin.

- [00355] The capability of an alkynyl phenyl-linked amine derivative compound to increase retinal cell viability and/or to enhance, promote, or prolong cell survival (that is, to extend the time period in which retinal cells, including retinal neuronal cells, are viable), and/or impair, inhibit, or impede degeneration as a direct or indirect result of the herein described stress may be determined by any one of several methods known to those skilled in the art. For example, changes in cell morphology in the absence and presence of the compound may be determined by visual inspection such as by light microscopy, confocal microscopy, or other microscopy methods known in the art. Survival of cells can also be determined by counting viable and/or nonviable cells, for instance. Immunochemical or immunohistological techniques (such as fixed cell staining or flow cytometry) may be used to identify and evaluate cytoskeletal structure (*e.g.*, by using antibodies specific for cytoskeletal proteins such as glial fibrillary acidic protein, fibronectin, actin, vimentin, tubulin, or the like) or to evaluate expression of cell markers as described herein. The effect of an alkynyl phenyl-linked amine derivative compound on cell integrity, morphology, and/or survival may also be determined by measuring the phosphorylation state of neuronal cell polypeptides, for example, cytoskeletal polypeptides (*see, e.g.*, Sharma et al., *J. Biol. Chem.* 274:9600-06 (1999); Li et al., *J. Neurosci.* 20:6055-62 (2000)). Cell survival or, alternatively cell death, may also be determined according to methods described herein and known in the art for measuring apoptosis (for example, annexin V binding, DNA fragmentation assays, caspase activation, marker analysis, *e.g.*, poly(ADP-ribose) polymerase (PARP), etc.).
- [00356] In the vertebrate eye, for example, a mammalian eye, the formation of A2E is a light-dependent process and its accumulation leads to a number of negative effects in the eye. These include destabilization of retinal pigment epithelium (RPE) membranes, sensitization of cells to blue-light damage, and impaired degradation of phospholipids. Products of the oxidation of A2E (and A2E related molecules) by molecular oxygen (oxiranes) were shown to induce DNA damage in cultured RPE cells. All these factors lead to a gradual decrease in visual acuity and eventually to vision loss. If reducing the formation of retinals during vision processes were possible, this reduction would lead to decreased amounts of A2E in the eye. Without wishing to be bound by theory, decreased accumulation of A2E may reduce or delay degenerative processes in the RPE and retina and thus may slow down or prevent vision loss in dry AMD and Stargardt's Disease.
- [00357] In another embodiment, methods are provided for treating and/or preventing degenerative diseases and disorders, including neurodegenerative retinal diseases and ophthalmic diseases, and retinal diseases and disorders as described herein. A subject in need of such treatment may be a human or non-human primate or other animal who has developed symptoms of a degenerative retinal disease or who is at risk for developing a degenerative retinal disease. As described herein a method is provided for treating (which includes preventing or prophylaxis) an ophthalmic disease or disorder by administering to a subject a composition comprising a pharmaceutically acceptable carrier and an alkynyl phenyl-linked amine derivative compound (*e.g.*, a compound having the structure of any one of Formulae (A)-(G) and (I)-(III), and substructures thereof.) As described herein, a method is provided for enhancing survival of neuronal cells such as retinal neuronal cells, including photoreceptor cells, and/or inhibiting degeneration of retinal

neuronal cells by administering the pharmaceutical compositions described herein comprising an alkynyl phenyl-linked amine derivative compound.

- [00358] Enhanced survival (or prolonged or extended survival) of one or more retinal cell types in the presence of an alkynyl phenyl-linked amine derivative compound indicates that the compound may be an effective agent for treatment of a degenerative disease, particularly a retinal disease or disorder, and including a neurodegenerative retinal disease or disorder. Cell survival and enhanced cell survival may be determined according to methods described herein and known to a skilled artisan including viability assays and assays for detecting expression of retinal cell marker proteins. For determining enhanced survival of photoreceptor cells, opsins may be detected, for instance, including the protein rhodopsin that is expressed by rods.
- [00359] In another embodiment, the subject is being treated for Stargardt's disease or Stargardt's macular degeneration. In Stargardt's disease, which is associated with mutations in the ABCA4 (also called ABCR) transporter, the accumulation of all-*trans*-retinal has been proposed to be responsible for the formation of a lipofuscin pigment, A2E, which is toxic towards retinal cells and causes retinal degeneration and consequently loss of vision.
- [00360] In yet another embodiment, the subject is being treated for age-related macular degeneration (AMD). In various embodiments, AMD can be wet- or dry-form. In AMD, vision loss primarily occurs when complications late in the disease either cause new blood vessels to grow under the macula or the macula atrophies. Without intending to be bound by any particular theory, the accumulation of all-*trans*-retinal has been proposed to be responsible for the formation of a lipofuscin pigment, *N*-retinylidene-*N*-retinylethanolamine (A2E) and A2E related molecules, which are toxic towards RPE and retinal cells and cause retinal degeneration and consequently loss of vision.
- [00361] A neurodegenerative retinal disease or disorder for which the compounds and methods described herein may be used for treating, curing, preventing, ameliorating the symptoms of, or slowing, inhibiting, or stopping the progression of, is a disease or disorder that leads to or is characterized by retinal neuronal cell loss, which is the cause of visual impairment. Such a disease or disorder includes but is not limited to age-related macular degeneration (including dry-form and wet-form of macular degeneration) and Stargardt's macular dystrophy.
- [00362] Age-related macular degeneration as described herein is a disorder that affects the macula (central region of the retina) and results in the decline and loss of central vision. Age-related macular degeneration occurs typically in individuals over the age of 55 years. The etiology of age-related macular degeneration may include both environmental influences and genetic components (*see, e.g.*, Lyengar et al., *Am. J. Hum. Genet.* 74:20-39 (2004) (Epub 2003 December 19); Kenealy et al., *Mol. Vis.* 10:57-61 (2004); Gorin et al., *Mol. Vis.* 5:29 (1999)). More rarely, macular degeneration occurs in younger individuals, including children and infants, and generally, these disorders results from a genetic mutation. Types of juvenile macular degeneration include Stargardt's disease (*see, e.g.*, Glazer et al., *Ophthalmol. Clin. North Am.* 15:93-100, viii (2002); Weng et al., *Cell* 98:13-23 (1999)); Doyme's honeycomb retinal dystrophy (*see, e.g.*, Kermani et al., *Hum. Genet.* 104:77-82 (1999)); Sorsby's fundus dystrophy, Malattia Levantine, fundus flavimaculatus, and autosomal dominant hemorrhagic macular dystrophy (*see also* Seddon et al., *Ophthalmology* 108:2060-67 (2001); Yates et al., *J. Med. Genet.* 37:83-7 (2000); Jaakson et al., *Hum. Mutat.* 22:395-403 (2003)). Geographic atrophy of the RPE is an advanced form of non-neovascular dry-type age-related macular degeneration, and is associated with atrophy of the choriocapillaris, RPE, and

retina.

- [00363] Stargardt's macular degeneration, a recessive inherited disease, is an inherited blinding disease of children. The primary pathologic defect in Stargardt's disease is also an accumulation of toxic lipofuscin pigments such as A2E in cells of the retinal pigment epithelium (RPE). This accumulation appears to be responsible for the photoreceptor death and severe visual loss found in Stargardt's patients. The compounds described herein may slow the synthesis of 11-*cis*-retinaldehyde (11cRAL or retinal) and regeneration of rhodopsin by inhibiting isomerase in the visual cycle. Light activation of rhodopsin results in its release of all-*trans*-retinal, which constitutes the first reactant in A2E biosynthesis. Treatment with alkynyl phenyl-linked amine derivative compounds may inhibit lipofuscin accumulation and thus delay the onset of visual loss in Stargardt's and AMD patients without toxic effects that would preclude treatment with an alkynyl phenyl-linked amine derivative compound. The compounds described herein may be used for effective treatment of other forms of retinal or macular degeneration associated with lipofuscin accumulation.
- [00364] Administration of an alkynyl phenyl-linked amine derivative compound to a subject can prevent formation of the lipofuscin pigment, A2E (and A2E related molecules), that is toxic towards retinal cells and causes retinal degeneration. In certain embodiments, administration of an alkynyl phenyl-linked amine derivative compound can lessen the production of waste products, *e.g.*, lipofuscin pigment, A2E (and A2E related molecules), ameliorate the development of AMD (*e.g.*, dry-form) and Stargardt's disease, and reduce or slow vision loss (*e.g.*, choroidal neovascularization and/or chorioretinal atrophy). In previous studies, with 13-*cis*-retinoic acid (Accutane® or Isotretinoin), a drug commonly used for the treatment of acne and an inhibitor of 11-*cis*-retinol dehydrogenase, has been administered to patients to prevent A2E accumulation in the RPE. However, a major drawback in this proposed treatment is that 13-*cis*-retinoic acid can easily isomerize to all-*trans*-retinoic acid. All-*trans*-retinoic acid is a very potent teratogenic compound that adversely affects cell proliferation and development. Retinoic acid also accumulates in the liver and may be a contributing factor in liver diseases.
- [00365] In yet other embodiments, an alkynyl phenyl-linked amine derivative compound is administered to a subject such as a human with a mutation in the ABCA4 transporter in the eye. The alkynyl phenyl-linked amine derivative compound can also be administered to an aging subject. As used herein, an aging human subject is typically at least 45, or at least 50, or at least 60, or at least 65 years old. In Stargardt's disease, which is associated with mutations in the ABCA4 transporter, the accumulation of all-*trans*-retinal has been proposed to be responsible for the formation of a lipofuscin pigment, A2E (and A2E related molecules), that is toxic towards retinal cells and causes retinal degeneration and consequently loss of vision. Without wishing to be bound by theory, an alkynyl phenyl-linked amine derivative compound described herein may be a strong inhibitor of an isomerase involved in the visual cycle. Treating patients with an alkynyl phenyl-linked amine derivative compound as described herein may prevent or slow the formation of A2E (and A2E related molecules) and can have protective properties for normal vision.
- [00366] In other certain embodiments, one or more of the compounds described herein may be used for treating other ophthalmic diseases or disorders, for example, glaucoma, retinal detachment, hemorrhagic retinopathy, retinitis pigmentosa, an inflammatory retinal disease, proliferative vitreoretinopathy, retinal dystrophy, hereditary optic neuropathy, Sorsby's fundus dystrophy, uveitis, a retinal injury, optical neuropathy, and retinal disorders associated with other neurodegenerative diseases such as Alzheimer's disease, multiple sclerosis, Parkinson's disease or other neurodegenerative diseases that affect brain cells, a retinal disorder associated with viral infection, or other conditions such as AIDS. A retinal disorder also

includes light damage to the retina that is related to increased light exposure (*i.e.*, overexposure to light), for example, accidental strong or intense light exposure during surgery; strong, intense, or prolonged sunlight exposure, such as at a desert or snow covered terrain; during combat, for example, when observing a flare or explosion or from a laser device, and the like. Retinal diseases can be of degenerative or non-degenerative nature. Non-limiting examples of degenerative retinal diseases include age-related macular degeneration, and Stargardt's macular dystrophy. Examples of non-degenerative retinal diseases include but are not limited hemorrhagic retinopathy, retinitis pigmentosa, optic neuropathy, inflammatory retinal disease, diabetic retinopathy, diabetic maculopathy, retinal blood vessel occlusion, retinopathy of prematurity, or ischemia reperfusion related retinal injury, proliferative vitreoretinopathy, retinal dystrophy, hereditary optic neuropathy, Sorsby's fundus dystrophy, uveitis, a retinal injury, a retinal disorder associated with Alzheimer's disease, a retinal disorder associated with multiple sclerosis, a retinal disorder associated with Parkinson's disease, a retinal disorder associated with viral infection, a retinal disorder related to light overexposure, and a retinal disorder associated with AIDS.

- [00367] In other certain embodiments, at least one of the compounds described herein may be used for treating, curing, preventing, ameliorating the symptoms of, or slowing, inhibiting, or stopping the progression of, certain ophthalmic diseases and disorders including but not limited to diabetic retinopathy, diabetic maculopathy, diabetic macular edema, retinal ischemia, ischemia-reperfusion related retinal injury, and retinal blood vessel occlusion (including venous occlusion and arterial occlusion).
- [00368] Diabetic retinopathy is a leading cause of blindness in humans and is a complication of diabetes. Diabetic retinopathy occurs when diabetes damages blood vessels inside the retina. Non-proliferative retinopathy is a common, usually mild form that generally does not interfere with vision. Abnormalities are limited to the retina, and vision is impaired only if the macula is involved. If left untreated retinopathy can progress to proliferative retinopathy, the more serious form of diabetic retinopathy. Proliferative retinopathy occurs when new blood vessels proliferate in and around the retina. Consequently, bleeding into the vitreous, swelling of the retina, and/or retinal detachment may occur, leading to blindness.
- [00369] Other ophthalmic diseases and disorders that may be treated using the methods and compositions described herein include diseases, disorders, and conditions that are associated with, exacerbated by, or caused by ischemia in the retina. Retinal ischemia includes ischemia of the inner retina and the outer retina. Retinal ischemia can occur from either choroidal or retinal vascular diseases, such as central or branch retinal vision occlusion, collagen vascular diseases and thrombocytopenic purpura. Retinal vasculitis and occlusion is seen with Eales disease and systemic lupus erythematosus.
- [00370] Retinal ischemia may be associated with retinal blood vessel occlusion. In the United States, both branch and central retinal vein occlusions are the second most common retinal vascular diseases after diabetic retinopathy. About 7% to 10% of patients who have retinal venous occlusive disease in one eye eventually have bilateral disease. Visual field loss commonly occurs from macular edema, ischemia, or vitreous hemorrhage secondary to disc or retinal neovascularization induced by the release of vascular endothelial growth factor.
- [00371] Arteriosclerosis at sites of retinal arteriovenous crossings (areas in which arteries and veins share a common adventitial sheath) causes constriction of the wall of a retinal vein by a crossing artery. The constriction results in thrombus formation and subsequent occlusion of the vein. The blocked vein may lead to macular edema and hemorrhage secondary to breakdown in the blood-retina barrier in the area drained by the vein, disruption of circulation with turbulence in venous flow, endothelial damage, and

ischemia. Clinically, areas of ischemic retina appear as feathery white patches called cotton-wool spots.

- [00372] Branch retinal vein occlusions with abundant ischemia cause acute central and paracentral visual field loss corresponding to the location of the involved retinal quadrants. Retinal neovascularization due to ischemia may lead to vitreous hemorrhage and subacute or acute vision loss.
- [00373] Two types of central retinal vein occlusion, ischemic and nonischemic, may occur depending on whether widespread retinal ischemia is present. Even in the nonischemic type, the macula may still be ischemic. Approximately 25% central retinal vein occlusion is ischemic. Diagnosis of central retinal vein occlusion can usually be made on the basis of characteristic ophthalmoscopic findings, including retinal hemorrhage in all quadrants, dilated and tortuous veins, and cotton-wool spots. Macular edema and foveal ischemia can lead to vision loss. Extracellular fluid increases interstitial pressure, which may result in areas of retinal capillary closure (*i.e.*, patchy ischemic retinal whitening) or occlusion of a cilioretinal artery.
- [00374] Patients with ischemic central retinal vein occlusion are more likely to present with a sudden onset of vision loss and have visual acuity of less than 20/200, a relative afferent pupillary defect, abundant intraretinal hemorrhages, and extensive nonperfusion on fluorescein angiography. The natural history of ischemic central retinal vein occlusion is associated with poor outcomes: eventually, approximately two-thirds of patients who have ischemic central retinal vein occlusion will have ocular neovascularization and one-third will have neovascular glaucoma. The latter condition is a severe type of glaucoma that may lead to rapid visual field and vision loss, epithelial edema of the cornea with secondary epithelial erosion and predisposition to bacterial keratitis, severe pain, nausea and vomiting, and, eventually, phthisis bulbi (atrophy of the globe with no light perception).
- [00375] As used herein, a patient (or subject) may be any mammal, including a human, that may have or be afflicted with a neurodegenerative disease or condition, including an ophthalmic disease or disorder, or that may be free of detectable disease. Accordingly, the treatment may be administered to a subject who has an existing disease, or the treatment may be prophylactic, administered to a subject who is at risk for developing the disease or condition. Treating or treatment refers to any indicia of success in the treatment or amelioration of an injury, pathology or condition, including any objective or subjective parameter such as abatement; remission; diminishing of symptoms or making the injury, pathology, or condition more tolerable to the patient; slowing in the rate of degeneration or decline; making the final point of degeneration less debilitating; or improving a subject's physical or mental well-being.
- [00376] The treatment or amelioration of symptoms can be based on objective or subjective parameters; including the results of a physical examination. Accordingly, the term "treating" includes the administration of the compounds or agents described herein to treat pain, hyperalgesia, allodynia, or nociceptive events and to prevent or delay, to alleviate, or to arrest or inhibit development of the symptoms or conditions associated with pain, hyperalgesia, allodynia, nociceptive events, or other disorders. The term "therapeutic effect" refers to the reduction, elimination, or prevention of the disease, symptoms of the disease, or sequelae of the disease in the subject. Treatment also includes restoring or improving retinal neuronal cell functions (including photoreceptor function) in a vertebrate visual system, for example, such as visual acuity and visual field testing etc., as measured over time (*e.g.*, as measured in weeks or months). Treatment also includes stabilizing disease progression (*i.e.*, slowing, minimizing, or halting the progression of an ophthalmic disease and associated symptoms) and minimizing additional degeneration of a vertebrate visual system. Treatment also includes prophylaxis and refers to the administration of an alkynyl phenyl-linked amine derivative compound to a subject to prevent degeneration or further degeneration or

deterioration or further deterioration of the vertebrate visual system of the subject and to prevent or inhibit development of the disease and/or related symptoms and sequelae.

- [00377] Various methods and techniques practiced by a person skilled in the medical and ophthalmological arts to determine and evaluate a disease state and/or to monitor and assess a therapeutic regimen include, for example, fluorescein angiogram, fundus photography, indocyanine green dye tracking of the choroidal circulatory system, ophthalmoscopy, optical coherence tomography (OCT), and visual acuity testing.
- [00378] A fluorescein angiogram involves injecting a fluorescein dye intravenously and then observing any leakage of the dye as it circulates through the eye. Intravenous injection of indocyanine green dye may also be used to determine if vessels in the eye are compromised, particularly in the choroidal circulatory system that is just behind the retina. Fundus photography may be used for examining the optic nerve, macula, blood vessels, retina, and the vitreous. Microaneurysms are visible lesions in diabetic retinopathy that may be detected in digital fundus images early in the disease (*see, e.g.*, U.S. Patent Application Publication No. 2007/0002275). An ophthalmoscope may be used to examine the retina and vitreous. Ophthalmoscopy is usually performed with dilated pupils, to allow the best view inside the eye. Two types of ophthalmoscopes may be used: direct and indirect. The direct ophthalmoscope is generally used to view the optic nerve and the central retina. The periphery, or entire retina, may be viewed by using an indirect ophthalmoscope. Optical coherence tomography (OCT) produces high resolution, high speed, non-invasive, cross-sectional images of body tissue. OCT is noninvasive and provides detection of microscopic early signs of disruption in tissues.
- [00379] A subject or patient refers to any vertebrate or mammalian patient or subject to whom the compositions described herein can be administered. The term "vertebrate" or "mammal" includes humans and non-human primates, as well as experimental animals such as rabbits, rats, and mice, and other animals, such as domestic pets (such as cats, dogs, horses), farm animals, and zoo animals. Subjects in need of treatment using the methods described herein may be identified according to accepted screening methods in the medical art that are employed to determine risk factors or symptoms associated with an ophthalmic disease or condition described herein or to determine the status of an existing ophthalmic disease or condition in a subject. These and other routine methods allow the clinician to select patients in need of therapy using the methods and formulations described herein.

wherein, the structures are as defined above and herein.

[00384] A pharmaceutical composition (*e.g.*, for oral administration or delivery by injection, or combined devices, or for application as an eye drop) may be in the form of a liquid or solid. A liquid pharmaceutical composition may include, for example, one or more of the following: sterile diluents such as water for injection, saline solution, preferably physiological saline, Ringer's solution, isotonic sodium chloride, fixed oils that may serve as the solvent or suspending medium, polyethylene glycols, glycerin, propylene glycol or other solvents; antibacterial agents; antioxidants; chelating agents; buffers and agents for the adjustment

of tonicity such as sodium chloride or dextrose. A parenteral preparation can be enclosed in ampules, disposable syringes or multiple dose vials made of glass or plastic. Physiological saline is commonly used as an excipient, and an injectable pharmaceutical composition or a composition that is delivered ocularly is preferably sterile.

- [00385] At least one alkynyl phenyl-linked amine derivative compound can be administered to human or other nonhuman vertebrates. In certain embodiments, the compound is substantially pure, in that it contains less than about 5% or less than about 1%, or less than about 0.1%, of other organic small molecules, such as contaminating intermediates or by-products that are created, for example, in one or more of the steps of a synthesis method. In other embodiments, a combination of one or more alkynyl phenyl-linked amine derivative compounds can be administered.
- [00386] An alkynyl phenyl-linked amine derivative compound can be delivered to a subject by any suitable means, including, for example, orally, parenterally, intraocularly, intravenously, intraperitoneally, intranasally (or other delivery methods to the mucous membranes, for example, of the nose, throat, and bronchial tubes), or by local administration to the eye, or by an intraocular or periocular device. Modes of local administration can include, for example, eye drops, intraocular injection or periocular injection. Periocular injection typically involves injection of the synthetic isomerization inhibitor, *i.e.*, alkynyl phenyl-linked amine derivative compound under the conjunctiva or into the Tenon's space (beneath the fibrous tissue overlying the eye). Intraocular injection typically involves injection of the alkynyl phenyl-linked amine derivative compound into the vitreous. In certain embodiments, the administration is non-invasive, such as by eye drops or oral dosage form, or as a combined device.
- [00387] An alkynyl phenyl-linked amine derivative compound can be formulated for administration using pharmaceutically acceptable (suitable) carriers or vehicles as well as techniques routinely used in the art. A pharmaceutically acceptable or suitable carrier includes an ophthalmologically suitable or acceptable carrier. A carrier is selected according to the solubility of the alkynyl phenyl-linked amine derivative compound. Suitable ophthalmological compositions include those that are administrable locally to the eye, such as by eye drops, injection or the like. In the case of eye drops, the formulation can also optionally include, for example, ophthalmologically compatible agents such as isotonicizing agents such as sodium chloride, concentrated glycerin, and the like; buffering agents such as sodium phosphate, sodium acetate, and the like; surfactants such as polyoxyethylene sorbitan mono-oleate (also referred to as Polysorbate 80), polyoxyl stearate 40, polyoxyethylene hydrogenated castor oil, and the like; stabilization agents such as sodium citrate, sodium edentate, and the like; preservatives such as benzalkonium chloride, parabens, and the like; and other ingredients. Preservatives can be employed, for example, at a level of from about 0.001 to about 1.0% weight/volume. The pH of the formulation is usually within the range acceptable to ophthalmologic formulations, such as within the range of about pH 4 to 8, or pH 5 to 7, or pH 6 to 7, or pH 4 to 7, or pH 5 to 8, or pH 6 to 8, or pH 4 to 6, or pH 5 to 6, or pH 7 to 8.
- [00388] For injection, the alkynyl phenyl-linked amine derivative compound can be provided in an injection grade saline solution, in the form of an injectable liposome solution, slow-release polymer system or the like. Intraocular and periocular injections are known to those skilled in the art and are described in numerous publications including, for example, Spaeth, Ed., *Ophthalmic Surgery: Principles of Practice*, W. B. Sanders Co., Philadelphia, Pa., 85-87, 1990.
- [00389] For delivery of a composition comprising at least one of the compounds described herein via a mucosal route, which includes delivery to the nasal passages, throat, and airways, the composition may be delivered

in the form of an aerosol. The compound may be in a liquid or powder form for intramucosal delivery. For example, the composition may be delivered via a pressurized aerosol container with a suitable propellant, such as a hydrocarbon propellant (*e.g.*, propane, butane, isobutene). The composition may be delivered via a non-pressurized delivery system such as a nebulizer or atomizer.

- [00390] Suitable oral dosage forms include, for example, tablets, pills, sachets, or capsules of hard or soft gelatin, methylcellulose or of another suitable material easily dissolved in the digestive tract. Suitable nontoxic solid carriers can be used which include, for example, pharmaceutical grades of mannitol, lactose, starch, magnesium stearate, sodium saccharin, talcum, cellulose, glucose, sucrose, magnesium carbonate, and the like. (*See, e.g., Remington: The Science and Practice of Pharmacy* (Gennaro, 21<sup>st</sup> Ed. Mack Pub. Co., Easton, PA (2005)).
- [00391] The alkynyl phenyl-linked amine derivative compounds described herein may be formulated for sustained or slow-release. Such compositions may generally be prepared using well known technology and administered by, for example, oral, periocular, intraocular, rectal or subcutaneous implantation, or by implantation at the desired target site. Sustained-release formulations may contain an agent dispersed in a carrier matrix and/or contained within a reservoir surrounded by a rate controlling membrane. Excipients for use within such formulations are biocompatible, and may also be biodegradable; preferably the formulation provides a relatively constant level of active component release. The amount of active compound contained within a sustained-release formulation depends upon the site of implantation, the rate and expected duration of release, and the nature of the condition to be treated or prevented.
- [00392] Systemic drug absorption of a drug or composition administered via an ocular route is known to those skilled in the art (*see, e.g., Lee et al., Int. J. Pharm.* 233:1-18 (2002)). In one embodiment, an alkynyl phenyl-linked amine derivative compound is delivered by a topical ocular delivery method (*see, e.g., Curr. Drug Metab.* 4:213-22 (2003)). The composition may be in the form of an eye drop, salve, or ointment or the like, such as, aqueous eye drops, aqueous ophthalmic suspensions, non-aqueous eye drops, and non-aqueous ophthalmic suspensions, gels, ophthalmic ointments, etc. For preparing a gel, for example, carboxyvinyl polymer, methyl cellulose, sodium alginate, hydroxypropyl cellulose, ethylene maleic anhydride polymer and the like can be used.
- [00393] The dose of the composition comprising at least one of the alkynyl phenyl-linked amine derivative compounds described herein may differ, depending upon the patient's (*e.g.*, human) condition, that is, stage of the disease, general health status, age, and other factors that a person skilled in the medical art will use to determine dose. When the composition is used as eye drops, for example, one to several drops per unit dose, preferably 1 or 2 drops (about 50  $\mu$ l per 1 drop), may be applied about 1 to about 6 times daily.
- [00394] Pharmaceutical compositions may be administered in a manner appropriate to the disease to be treated (or prevented) as determined by persons skilled in the medical arts. An appropriate dose and a suitable duration and frequency of administration will be determined by such factors as the condition of the patient, the type and severity of the patient's disease, the particular form of the active ingredient, and the method of administration. In general, an appropriate dose and treatment regimen provides the composition(s) in an amount sufficient to provide therapeutic and/or prophylactic benefit (*e.g.*, an improved clinical outcome, such as more frequent complete or partial remissions, or longer disease-free and/or overall survival, or a lessening of symptom severity). For prophylactic use, a dose should be sufficient to prevent, delay the onset of, or diminish the severity of a disease associated with neurodegeneration of retinal neuronal cells and/or degeneration of other mature retinal cells such as RPE cells. Optimal doses may generally be

determined using experimental models and/or clinical trials. The optimal dose may depend upon the body mass, weight, or blood volume of the patient.

- [00395] The doses of the alkynyl phenyl-linked amine derivative compounds can be suitably selected depending on the clinical status, condition and age of the subject, dosage form and the like. In the case of eye drops, an alkynyl phenyl-linked amine derivative compound can be administered, for example, from about 0.01 mg, about 0.1 mg, or about 1 mg, to about 25 mg, to about 50 mg, to about 90 mg per single dose. Eye drops can be administered one or more times per day, as needed. In the case of injections, suitable doses can be, for example, about 0.0001 mg, about 0.001 mg, about 0.01 mg, or about 0.1 mg to about 10 mg, to about 25 mg, to about 50 mg, or to about 90 mg of the alkynyl phenyl-linked amine derivative compound, one to seven times per week. In other embodiments, about 1.0 to about 30 mg of the alkynyl phenyl-linked amine derivative compound can be administered one to seven times per week.
- [00396] Oral doses can typically range from 1.0 to 1000 mg, one to four times, or more, per day. An exemplary dosing range for oral administration is from 10 to 250 mg one to three times per day. If the composition is a liquid formulation, the composition comprises at least 0.1% active compound at particular mass or weight (e.g., from 1.0 to 1000 mg) per unit volume of carrier, for example, from about 2% to about 60%.
- [00397] In certain embodiments, at least one alkynyl phenyl-linked amine compound described herein may be administered under conditions and at a time that inhibits or prevents dark adaptation of rod photoreceptor cells. In certain embodiments, the compound is administered to a subject at least 30 minutes (half hour), 60 minutes (one hour), 90 minutes (1.5 hour), or 120 minutes (2 hours) prior to sleeping. In certain embodiments, the compound may be administered at night before the subject sleeps. In other embodiments, a light stimulus may be blocked or removed during the day or under normal light conditions by placing the subject in an environment in which light is removed, such as placing the subject in a darkened room or by applying an eye mask over the eyes of the subject. When the light stimulus is removed in such a manner or by other means contemplated in the art, the agent may be administered prior to sleeping.
- [00398] The doses of the compounds that may be administered to prevent or inhibit dark adaptation of a rod photoreceptor cell can be suitably selected depending on the clinical status, condition and age of the subject, dosage form and the like. In the case of eye drops, the compound (or the composition comprising the compound) can be administered, for example, from about 0.01 mg, about 0.1 mg, or about 1 mg, to about 25 mg, to about 50 mg, to about 90 mg per single dose. #### EXAMPLES

[00402] Unless otherwise noted, reagents and solvents were used as received from commercial suppliers.

Anhydrous solvents and oven-dried glassware were used for synthetic transformations generally considered sensitive to moisture and/or oxygen. Flash column chromatography and thin layer chromatography (TLC) were performed on silica gel unless otherwise noted. Proton and carbon nuclear magnetic resonance spectra were obtained on either a Varian VnmrS 400 at 400 MHz for proton and 100 MHz for carbon, or on Bruker AMX 500 or 300 spectrometers at 500 or 300 MHz for proton and 125 or 75 MHz for carbon, as noted. Spectra are given in ppm ( $\delta$ ) and coupling constants,  $J$ , are reported in Hertz. For proton spectra either tetramethylsilane was used as an internal standard or the solvent peak was used as the reference peak. For carbon spectra the solvent peak was used as the reference. Chiral HPLC Analyses were obtained using a Chiralpak IA column (4.6 mm x 250 mm, 5 $\mu$ ) with diode array detection. The flow rate was 1 mL/min.

EXAMPLE 1

## PREPARATION OF 1-(3-(3-AMINOPROPYL)PHENYL)-3-ETHYLPENT-1-YN-3-OL

[00403] 1-(3-(3-Aminopropyl)phenyl)-3-ethylpent-1-yn-3-ol was prepared following the method shown in Scheme 1:

SCHEME 1

[00404] **Step 1:** To a stirred solution of 3-(3-bromophenyl)propanoic acid (1) (25.0 g, 109.1 mmole) in  $\text{CH}_2\text{Cl}_2$  (150 ml) was added oxalyl chloride (27.7 g, 218.3 mmol) followed by DMF (2 drops). The solution was stirred

at room temperature overnight. The resulting mixture was concentrated under reduced pressure to give the crude acid chloride which was used immediately in the next reaction.

- [00405] **Step 2:** The crude material was dissolved in anhydrous THF (150 ml) and cooled in an ice bath. Ammonia gas was bubbled into the solution for 3-4 minutes and the mixture was warmed to room temperature and stirred overnight. The mixture was concentrated under reduced pressure. Saturated NaHCO<sub>3</sub> (100 ml) was added to the residue and the mixture was extracted with EtOAc (2 X 200 ml). The combined organics were dried over Na<sub>2</sub>SO<sub>4</sub> and concentrated under reduced pressure to give amide **2** as a white solid. Yield (23.9 g, 96%): <sup>1</sup>H NMR (400 MHz, DMSO-*d*<sub>6</sub>) δ 7.40 (s, 1H), 7.35 (dt, *J* = 6.4, 2.4 Hz, 1H), 7.26 (br s, 1H), 7.18-7.24 (m, 2H), 6.75 (br s, 1H), 2.78 (t, *J* = 7.6 Hz, 2H), 2.34 (t, *J* = 7.6 Hz, 2H).
- [00406] **Step 3:** To an ice-cold solution of amide **2** (23.85 g, 104.6 mmol) in anhydrous THF (250 ml) was added BH<sub>3</sub>·THF (209 ml of a 1.0 M solution in THF, 209 mmol). The solution was warmed to room temperature and stirred for 18 h. The reaction was quenched by the slow addition of 6 N HCl until pH 1 was achieved. The solution was then stirred at room temperature for 4 h. at which time the pH was adjusted to >10 with the addition of 50% aqueous NaOH. The solution was extracted with EtOAc (2 X 250 ml). The combined organic layers were washed with brine, dried over Na<sub>2</sub>SO<sub>4</sub> and concentrated under reduced pressure to give the crude amine which was used immediately in the next reaction.
- [00407] **Step 4:** Crude 3-(3-bromophenyl)propan-1-amine (ca. 104.6 mmol) was stirred with ethyl trifluoroacetate (30 ml) overnight. The mixture was concentrated under reduced pressure. Purification by flash chromatography (20% EtOAc-hexanes) gave trifluoroacetamide **3**. Yield (21.1 g, 62%): <sup>1</sup>H NMR (400 MHz, DMSO-*d*<sub>6</sub>) δ 9.40 (br s, 1H), 7.43 (s, 1H), 7.36 (dt, *J* = 7.2, 2.0 Hz, 1H), 7.19-7.25 (m, 2H), 3.16 (q, *J* = 6.8 Hz, 2H), 2.57 (t, *J* = 7.6 Hz, 2H), 1.77 (quint., *J* = 7.2 Hz, 2H).
- [00408] **Step 5:** To a degassed solution of *N*-(3-(3-bromophenyl)propyl)-2,2,2-trifluoroacetamide (**3**) (0.930 g, 3 mmol) and 3-ethylpent-1-yn-3-ol (**4**) (0.670 g, 6 mmol) in triethylamine (4 mL) and DMF (12 mL) was added PdCl<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub> (0.053 g, 0.075 mmol), tri-*o*-tolylphosphine (0.046 g, 0.15 mmol), and CuI (0.014 g, 0.075 mmol). The resulting mixture was degassed and stirred under argon at 90 °C for 6 h. The mixture was cooled to room temperature then concentrated under reduced pressure and diluted with EtOAc (100 mL) and water (70 mL). After vigorous shaking, the layers were separated. The organic layer was treated with charcoal, dried over MgSO<sub>4</sub>, filtered, and concentrated under reduced pressure. Purification by flash column chromatography (7 to 60% EtOAc-hexanes gradient) gave *N*-(3-(3-(3-ethyl-3-hydroxypentyl)phenyl)propyl)-2,2,2-trifluoroacetamide (**5**) as a yellow oil. Yield (0.663 g, 65%): <sup>1</sup>H NMR (400 MHz, DMSO-*d*<sub>6</sub>) δ 9.40 (s, 1H), 7.17-7.28 (m, 4H), 5.11 (s, 1H), 3.16 (q, *J* = 7.2 Hz, 2H), 2.56 (t, *J* = 7.2 Hz, 2H), 1.76 (quint, *J* = 7.2 Hz, 2H), 1.53-1.67 (m, 4H), 0.97 (t, *J* = 7.2 Hz, 6H).
- [00409] **Step 6:** *N*-(3-(3-(3-ethyl-3-hydroxypentyl)phenyl)propyl)-2,2,2-trifluoroacetamide (**5**) (0.660 g, 1.93 mmol) was dissolved in MeOH (15 mL), and an aqueous solution of K<sub>2</sub>CO<sub>3</sub> (0.42 g in 3 mL water, 3.0 mmol) was added. The resulting mixture was stirred at 45 °C for 4 h. After cooling, the reaction mixture was concentrated under reduced pressure and diluted with EtOAc (50 mL) and water (50 mL). After vigorous shaking, the layers were separated. The organic layer was dried over Na<sub>2</sub>SO<sub>4</sub>, filtered, and concentrated under reduced pressure. Purification by flash column chromatography (72:8:20 to 90:10:0 EtOAc/7 M NH<sub>3</sub> in MeOH/hexanes) gave Example 1 as a clear oil. Yield (0.421 g, 89%): <sup>1</sup>H NMR (400 MHz, DMSO-*d*<sub>6</sub>) δ 7.15-7.26 (m, 4H), 5.11 (s, 1H), 2.56 (t, *J* = 7.6 Hz, 2H), 2.47 (t, *J* = 5.2 Hz, 2H), 1.55-1.65 (m, 6H), 1.39 (br s, 2H), 0.97 (t, *J* = 7.6 Hz, 6H).

[00837] 3-(3-(Cyclopropylethynyl)phenyl)propan-1-amine was prepared following the method shown in Scheme 21.

SCHEME 21

[00838] **Step 1:** To suspension of  $\text{LiAlH}_4$  (0.5 g, 1.3 mmol) in diethyl ether (25 mL) was added 3-bromocinnamic acid (**83**, 1.0 g, 4 mmol), in portions, at RT. The resulting suspension was stirred for 3 hours. The reaction was quenched by the successive addition of 15% aq. NaOH solution (1 mL) and water. The resulting white suspension was filtered through a pad of Celite. The filter cake was washed with ether and then ethyl acetate. The filtrate was concentrated to afford crude **8** as yellow oil. Yield (0.7g, 74%).  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$  7.10-7.35 (m, 4H), 3.65 (t,  $J = 6.5$  Hz, 2H), 2.68 (t,  $J = 7.8$  Hz, 2H), 1.82-1.91 (m, 2H).

[00839] **Step 2:** To a stirred solution of alcohol **8** (1.0 g, 4.6 mmol) and triethylamine (1.0 mL, 99 mmol) in DCM (15 mL) was added MsCl (0.7 mL, 66 mmol) over a period of 5 min at 0 °C. The resulting mixture was stirred at 0 °C for 30 min, brought up to room temp and stirred for 30 min during which the conversion was complete. The mixture poured into water and extracted with ethyl acetate. The combined organic layer was washed with water and brine, and dried over anhydrous  $\text{Na}_2\text{SO}_4$ . This was filtered and concentrated to afford the mesylate **84** as a yellow oil (1.0 g, 73%). This crude product was utilized immediately for the next transformation.

[00840] **Step 3:** To a solution of crude mesylate **84** (1.0 g, 3.4 mmol) in DMF (8 mL) was added  $\text{NaN}_3$  (0.44 g, 6.8 mmol). The resulting mixture was stirred at 80 °C for 1 h. This was cooled, poured into water and extracted with ethyl acetate. The combined organics were washed with water and brine, dried over anhydrous  $\text{Na}_2\text{SO}_4$ . Filtration, followed by concentration under reduced pressure afforded **85** as a colorless oil. Yield (0.7 g, 85%).  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$  7.32-7.38 (m, 2H), 7.09-7.20 (m, 2H), 3.29 (t,  $J = 6.4$  Hz, 2H), 2.68 (t,  $J = 7.2$  Hz, 2H), 1.84-1.94 (m, 2H).

The mixture was stirred for 48 hr during which the conversion was found to be complete. The solvent was removed under reduced pressure and the resulting residue was carried forward to the next step.
- [00842] **Step 5:** The amine **86** was dissolved in 1, 4-dioxane (300 mL) and water (180 mL).  $\text{K}_2\text{CO}_3$  (17.2 g, 120 mmol),  $(\text{Boc})_2\text{O}$  (14 mL, 60 mmol) were successively added and the mixture was stirred for 2 hour. After removal of 1,4-dioxane under reduced pressure, the aqueous phase was extracted with ethyl acetate. The organic phase was washed with water and brine, dried over anhydrous  $\text{Na}_2\text{SO}_4$ . This was concentrated to afford crude yellow oil. Purification by flash chromatography (0-9 % ethyl acetate: Hexane gradient) gave **87** as pale yellow oil. The resulting mixture was degassed and stirred under nitrogen at 90 °C for overnight. The mixture was cooled to room temperature and concentrated under reduced pressure. The residue was partitioned between water and ethyl acetate. The organic layer was dried over anhydrous  $\text{Na}_2\text{SO}_4$ , filtered, and concentrated under reduced pressure. Then a solution of methyl iodide (2.276 g, 16.03 mmol) in DMSO (2 mL) was added and the reaction mixture was stirred at

room temperature for 66 hr. Aqueous  $\text{NH}_4\text{Cl}$  (25%, 100 mL) was added and the product was extracted with EtOAc (3x70 mL). Combined organic layers were washed with brine, dried over anhydrous  $\text{MgSO}_4$ , filtered and the filtrate was concentrated under reduced pressure to give *N*-methylcarbamate **109** as a light yellowish liquid with a low boiling point. Yield (1.595 g, 76%);  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$  5.74 (ddt,  $J$  = 16.8, 10.6, 5.7 Hz, 1H), 5.06-5.13 (m, 2H), 3.79 (d,  $J$  = 5.5 Hz, 2H), 2.80 (s, 3H), 1.43 (s, 9H).

## IN VITRO ISOMERASE INHIBITION ASSAY

[001088] The capability of alkynyl phenyl-linked amine derivative compounds to inhibit the activity of a visual cycle isomerase was determined.

[001089] Isomerase inhibition reactions were performed essentially as described (Stecher *et al.*, *J. Biol. Chem.* 274:8577-85 (1999); *see also* Golczak *et al.*, *Proc. Natl. Acad. Sci. USA* 102:8162-67 (2005)). Bovine Retinal Pigment Epithelium (RPE) microsome membranes were the source of a visual cycle isomerase.

RPE Microsome Membrane Preparation

[001090] Bovine RPE microsome membrane extracts were prepared according to methods described (Golczak *et al.*, *Proc. Natl. Acad. Sci. USA* 102:8162-67 (2005)) and stored at  $-80^\circ\text{C}$ . Crude RPE microsome extracts were thawed in a  $37^\circ\text{C}$  water bath, and then immediately placed on ice. 50 ml crude RPE microsomes were placed into a 50 ml Teflon-glass homogenizer (Fisher Scientific, catalog no. 0841416M) on ice, powered by a hand-held DeWalt drill, and homogenized ten times up and down on ice under maximum speed. This process was repeated until the crude RPE microsome solution was homogenized. The homogenate was then subjected to centrifugation (50.2 Ti rotor (Beckman, Fullerton, CA), 13,000 RPM; 15360 Rcf) for 15 minutes at  $4^\circ\text{C}$ . The supernatant was collected and subjected to centrifugation at 42,000 RPM (160,000 Rcf; 50.2 Ti rotor) for 1 hour at  $4^\circ\text{C}$ . The supernatant was removed, and the pellets were suspended in 12 ml (final volume) cold 10 mM MOPS buffer, pH 7.0. The resuspended RPE membranes in 5 ml aliquots were homogenized in a glass-to-glass homogenizer (Fisher Scientific, catalog no. K885500-0021) to high homogeneity. Protein concentration was quantified using the BCA protein assay according to the manufacturer's protocol (Pierce, Rockford, IL). The homogenized RPE preparations were stored at  $-80^\circ\text{C}$ .

Isolation of Human Apo Cellular Retinaldehyde-Binding Protein (CRALBP)

[001091] Recombinant human apo cellular retinaldehyde-binding protein (CRALBP) was cloned and expressed according to standard methods in the molecular biology art (*see* Crabb *et al.*, *Protein Science* 7:746-57 (1998); Crabb *et al.*, *J. Biol. Chem.* 263:18688-92 (1988)). Briefly, total RNA was prepared from confluent ARPE19 cells (American Type Culture Collection, Manassas, VA), cDNA was synthesized using an oligo(dT)<sub>12-18</sub> primer, and then DNA encoding CRALBP was amplified by two sequential polymerase chain reactions (*see* Crabb *et al.*, *J. Biol. Chem.* 263:18688-92 (1988); Intres, *et al.*, *J. Biol. Chem.* 269:25411-18 (1994); GenBank Accession No. L34219.1). The PCR product was sub-cloned into pTrcHis2-TOPO TA vector according to the manufacturer's protocol (Invitrogen Inc., Carlsbad, CA; catalog no. K4400-01), and then the sequence was confirmed according to standard nucleotide sequencing techniques. Recombinant 6xHis-tagged human CRALBP was expressed in One Shot TOP 10 chemically competent *E. coli* cells (Invitrogen), and the recombinant polypeptide was isolated from *E. coli* cell lysates by nickel affinity chromatography using nickel (Ni) Sepharose XK16-20 columns for HPLC (Amersham Bioscience, Pittsburgh, PA; catalog no. 17-5268-02). The purified 6xHis-tagged human CRALBP was dialyzed against 10 mM bis-tris-Propane (BTP) and analyzed by SDS-PAGE. The molecular weight of the recombinant human CRALBP was approximately 39 kDal.

Isomerase Assay

- [001092] Alkynyl phenyl-linked amine derivative compounds and control compounds were reconstituted in ethanol to 0.1 M. Ten-fold serial dilutions ( $10^{-2}$ ,  $10^{-3}$ ,  $10^{-4}$ ,  $10^{-5}$ ,  $10^{-6}$  M) in ethanol of each compound were prepared for analysis in the isomerase assay.
- [001093] The isomerase assay was performed in 10 mM bis-tris-propane (BTP) buffer, pH 7.5, 0.5% BSA (diluted in BTP buffer), 1 mM sodium pyrophosphate, 20  $\mu$ M all-trans retinol (in ethanol), and 6  $\mu$ M apo-CRALBP. The test compounds (2  $\mu$ l) (final 1/15 dilution of serial dilution stocks) were added to the above reaction mixture to which RPE microsomes were added. The same volume of ethanol was added to the control reaction (absence of test compound). Bovine RPE microsomes (9  $\mu$ l) (see above) were then added, and the mixtures transferred to 37° C to initiate the reaction (total volume = 150  $\mu$ l). The reactions were stopped after 30 minutes by adding methanol (300  $\mu$ l). Heptane was added (300  $\mu$ l) and mixed into the reaction mixture by pipetting. Retinoid was extracted by agitating the reaction mixtures, followed by centrifugation in a microcentrifuge. The upper organic phase was transferred to HPLC vials and then analyzed by HPLC using an Agilent 1100 HPLC system with normal phase column: SILICA (Agilent Technologies, dp 5 $\mu$ , 4.6mmX, 25CM; running method had flow rate of 1.5 ml/min; injection volume 100  $\mu$ l). The solvent components were 20% of 2% isopropanol in EtOAc and 80% of 100% hexane.
- [001094] The area under the  $A_{318}$  nm curve represents the 11-cis retinol peak, which is calculated by Agilent Chemstation software and recorded manually. The  $IC_{50}$  values (concentration of compound that gives 50% inhibition of 11-cis retinol formation in vitro) are calculated using GraphPad Prism® 4 Software (Irvine, CA). All tests are performed in duplicate.
- [001095] The concentration dependent effect of the compounds disclosed herein on the retinol isomerization reaction can also be evaluated with a recombinant human enzyme system. In particular, the *in vitro* isomerase assay was performed essentially as in Golczak et al. 2005, PNAS 102: 8162-8167, ref. 3). A homogenate of HEK293 cell clone expressing recombinant human RPE65 and LRAT were the source of the visual enzymes, and exogenous all-trans-retinol (about 20 $\mu$ M) was used as the substrate. Recombinant human CRALBP (about 80ug/mL) was added to enhance the formation of 11cis-retinal. The 200  $\mu$ L Bis-Tris Phosphate buffer (10mM, pH 7.2) based reaction mixture also contains 0.5% BSA, and 1mM NaPPi. In this assay, the reaction was carried out at 37 °C in duplicates for one hour and was terminated by addition of 300  $\mu$ L methanol. The amount of reaction product, 11-cis-retinol, was measured by HPLC analysis following Heptane extraction of the reaction mixture. The Peak Area Units (PAUs) corresponding to 11cis-retinol in the HPLC chromatograms were recorded and concentration dependent curves analyzed by GraphPad Prism for  $IC_{50}$  values. The ability of the numerous compounds disclosed herein to inhibit isomerization reaction is quantified and the respective  $IC_{50}$  value is determined. The tables below summarises the  $IC_{50}$  values of various compounds of the present invention determined by either of the above two methods. Figure 1 is a representative figure of the  $IC_{50}$  determination of the compound of Example 2. Other  $IC_{50}$ s for human and bovine in vitro data are provided in Tables 14A and 14B.

## EXAMPLE 194

## IN VIVO MURINE ISOMERASE ASSAY

[001096] The capability of alkynyl phenyl-linked amine derivatives to inhibit isomerase is determined by an *in vivo* murine isomerase assay. Brief exposure of the eye to intense light ("photobleaching" of the visual pigment or simply "bleaching") is known to photo-isomerize almost all 11-*cis*-retinal in the retina. The recovery of 11-*cis*-retinal after bleaching can be used to estimate the activity of isomerase *in vivo*. Delayed recovery, as represented by lower 11-*cis*-retinal oxime levels, indicates inhibition of isomerization reaction. Procedures were performed essentially as described by Golczak et al., *Proc. Natl. Acad. Sci. USA* 102:8162-67 (2005). See also Deigner et al., *Science*, 244: 968-71 (1989); Gollapalli et al., *Biochim Biophys Acta*. 1651: 93-101 (2003); Parish, et al., *Proc. Natl. Acad. Sci. USA*, 14609-13 (1998); Radu, et al., *Proc Natl Acad Sci USA* 101: 5928-33 (2004).

[001097] Six-week old dark-adapted CD-1 (albino) male mice were orally gavaged with compound (0.03 – 3 mg/kg) dissolved in 100  $\mu$ l corn oil containing 10% ethanol (five animals per group). Mice were gavaged with the alkynyl phenyl derivative compounds described Examples 2, 18, 19, 100 and 101. After 2-24 hours in the dark, the mice were exposed to photobleaching of 5,000 lux of white light for 10 minutes. The mice were allowed to recover 2 hours in the dark. The animals were then sacrificed by carbon dioxide inhalation. Retinoids were extracted from the eye and the regeneration of 11-*cis*-retinal was assessed at various time intervals.

Eye Retinoid Extraction

- [001098] All steps were performed in darkness with minimal redlight illumination (low light darkroom lights and redfiltered flashlights for spot illumination as needed) (*see, e.g., Maeda et al., J. Neurochem* 85:944-956, 2003; Van Hooser *et al., J Biol Chem* 277:19173-82, 2002). After the mice were sacrificed, the eyes were immediately removed and placed in liquid nitrogen for storage.
- [001099] The eyes were placed in 500  $\mu$ L of bis-tris propane buffer (10 mM, pH ~7.3) and 20  $\mu$ L of 0.8M hydroxile amine (pH~7.3). The eyes were cut up into small pieces with small iris scissors and then thoroughly homogenized at 30000 rpm with a mechanical homogenizer (Polytron PT 1300 D) in the tube until no visible tissue remained. 500  $\mu$ L of methanol and 500  $\mu$ L of heptane were added to each tube. The tubes were attached to a vortexer so that the contents were mixed thoroughly for 15 minutes in room temperature. The organic phase was separated from the aqueous phase by centrifugation for 10min at 13K rpm, 4 °C. 240  $\mu$ L of the solution from the top layer (organic phase) was removed and transferred to clean 300  $\mu$ l glass inserts in HPLC vials using glass pipette and the vials were crimped shut tightly.
- [001100] The samples were analyzed on an Agilent 1100 HPLC system with normal phase column: SILICA (Beckman Coutlier, dp 5  $\mu$ m, 4.6 mM x 250 mM). The running method has a flow rate of 1.5ml/min; solvent components are 15% solvent 1 (1% isopropanol in ethyl acetate), and 85% solvent 2 (100% hexanes). Loading volume for each sample is 100  $\mu$ l; detection wavelength is 360nm. The area under the curve for 11-cis retinal oxime was calculated by Agilent Chemstation software and was recorded manually. Data processing was performed using Prizm software.
- [001101] Positive control mice (no compound administered) were sacrificed fully dark-adapted and the eye retinoids analyzed. Light (bleached) control mice (no compound administered) were sacrificed and retinoids isolated and analyzed immediately after light treatment.
- [001102] A dose response in vivo isomerase inhibition study was performed with the compounds of Examples 2, 18, 19, 100, and 101 (Compounds 2, 18, 19, 100 and 101). Male Balb/c mice (8/group) were dosed orally with 0.03, 0.1, 0.3, 1 and 3 mg/kg of Compound 2-HCl, Compound 18-HCl, Compound 100-HCl, or Compound 101-HCl in sterile water as solution, and photobleached 4 hours after dosing. Animals that received Compound-19 HCl were orally dosed with 0.01 and 1 mg/kg of compound in sterile water as solution, and photobleached 4 hours after dosing. Recovery and retinoid analysis were performed as described above. Dark control mice were vehicle-only treated, sacrificed fully dark adapted without light treatment, and analyzed. The concentration-dependent inhibition of isomerase activity at 4 hours post dosing of the Compounds 2, 18, and 19 are presented in Figures 2-4. Inhibition of 11-cis retinal (oxime) recovery for Compounds 2, 18, 19, 100 and 101 are presented in Figures 5-9 respectively. The estimated ED<sub>50</sub> (dose of compound that gives 50% inhibition of 11-cis retinal (oxime) recovery) are presented in Table 15B.
- [001103] A time course study was performed to determine the isomerase inhibitory activity of Compounds 2, 18 and 19. Male Balb/c mice (4/group) received 3 mg Compound 2-HCl, Compound 18-HCl or Compound 19-HCl (in water) per kg bodyweight orally, by gavage. The animals were then "photo-bleached" (5000 Lux white light for 10 minutes) at 2, 4, 8, 16 and 24 hours after dosing, and returned to darkness to allow recovery of the 11-cis-retinal content of the eyes. Mice were sacrificed 2 hours after bleaching, eyes were enucleated, and retinoid content was analyzed by HPLC. Results are presented in Figures 10-12.
- [001104] A single dose study of the compound of Example 36 (Compound 36) was performed, at 1mg/kg

and 5mg/kg oral dosing, 2, 4, 6, and 24 hours post bleaching. The experiments were carried out in CD1 male mice. Results were analyzed by HPLC. Results are presented in Figures 13 (1mg/kg) and 14 (5 mg/kg data) and in Table 15C. Example 36 was inactive at 1 mg/kg (Figure 13) and at 5 mg/kg was ~50% active at 2 and 6 h with full recovery at 24 h (Figure 14).

## PREPARATION OF RETINAL NEURONAL CELL CULTURE SYSTEM

[001105] This Example describes methods for preparing a long-term culture of retinal neuronal cells.

[001106] All compounds and reagents are obtained from Sigma Aldrich Chemical Corporation (St. Louis, MO) except as noted.

Retinal Neuronal Cell Culture

[001107] Porcine eyes are obtained from Kapowsin Meats, Inc. (Graham, WA). Eyes are enucleated, and muscle and tissue are cleaned away from the orbit. Eyes are cut in half along their equator and the neural retina is dissected from the anterior part of the eye in buffered saline solution, according to standard methods known in the art. Briefly, the retina, ciliary body, and vitreous are dissected away from the anterior half of the eye in one piece, and the retina is gently detached from the clear vitreous. Each retina is dissociated with papain (Worthington Biochemical Corporation, Lakewood, NJ), followed by inactivation with fetal bovine serum (FBS) and addition of 134 Kunitz units/ml of DNaseI. The enzymatically dissociated cells are triturated and collected by centrifugation, resuspended in Dulbecco's modified Eagle's medium (DMEM)/F12 medium (Gibco BRL, Invitrogen Life Technologies, Carlsbad, CA) containing 25 µg/ml of insulin, 100 µg/ml of transferrin, 60 µM putrescine, 30 nM selenium, 20 nM progesterone, 100 U/ml of penicillin, 100 µg/ml of streptomycin, 0.05 M Hepes, and 10% FBS. Dissociated primary retinal cells are plated onto Poly-D-lysine- and Matrigel- (BD, Franklin Lakes, NJ) coated glass coverslips that are placed in 24-well tissue culture plates (Falcon Tissue Culture Plates, Fisher Scientific, Pittsburgh, PA).

Cells are maintained in culture for 5 days to one month in 0.5 ml of media (as above, except with only 1% FBS) at 37 °C and 5% CO<sub>2</sub>.

#### Immunocytochemistry Analysis

- [001108] The retinal neuronal cells are cultured for 1, 3, 6, and 8 weeks, and the cells are analyzed by immunohistochemistry at each time point. Immunocytochemistry analysis is performed according to standard techniques known in the art. Rod photoreceptors are identified by labeling with a rhodopsin-specific antibody (mouse monoclonal, diluted 1:500; Chemicon, Temecula, CA). An antibody to mid-weight neurofilament (NFM rabbit polyclonal, diluted 1:10,000, Chemicon) is used to identify ganglion cells; an antibody to  $\beta$ 3-tubulin (G7121 mouse monoclonal, diluted 1:1000, Promega, Madison, WI) is used to generally identify interneurons and ganglion cells, and antibodies to calbindin (AB1778 rabbit polyclonal, diluted 1:250, Chemicon) and calretinin (AB5054 rabbit polyclonal, diluted 1:5000, Chemicon) are used to identify subpopulations of calbindin- and calretinin-expressing interneurons in the inner nuclear layer. Briefly, the retinal cell cultures are fixed with 4% paraformaldehyde (Polysciences, Inc, Warrington, PA) and/or ethanol, rinsed in Dulbecco's phosphate buffered saline (DPBS), and incubated with primary antibody for 1 hour at 37 °C. The cells are then rinsed with DPBS, incubated with a secondary antibody (Alexa 488- or Alexa 568-conjugated secondary antibodies (Molecular Probes, Eugene, OR)), and rinsed with DPBS. Nuclei are stained with 4', 6-diamidino-2-phenylindole (DAPI, Molecular Probes), and the cultures are rinsed with DPBS before removing the glass coverslips and mounting them with Fluoromount-G (Southern Biotech, Birmingham, AL) on glass slides for viewing and analysis.
- [001109] Survival of mature retinal neurons after varying times in culture is indicated by the histochemical analyses. Photoreceptor cells are identified using a rhodopsin antibody; ganglion cells are identified using an NFM antibody; and amacrine and horizontal cells are identified by staining with an antibody specific for calretinin.
- [001110] Cultures are analyzed by counting rhodopsin-labeled photoreceptors and NFM-labeled ganglion cells using an Olympus IX81 or CZX41 microscope (Olympus, Tokyo, Japan). Twenty fields of view are counted per coverslip with a 20x objective lens. Six coverslips are analyzed by this method for each condition in each experiment. Cells that are not exposed to any stressor are counted, and cells exposed to a stressor are normalized to the number of cells in the control.

#### EXAMPLE 196

##### EFFECT OF ALKYNYL PHENYL DERIVATIVE COMPOUNDS ON RETINAL CELL SURVIVAL

- [001111] This Example describes the use of the mature retinal cell culture system that comprises a cell stressor for determining the effects of an alkynyl phenyl derivative compound on the viability of the retinal cells.
- [001112] Retinal cell cultures are prepared as described in Example 195. A2E is added as a retinal cell stressor. After culturing the cells for 1 week, a chemical stress, A2E, is applied. A2E is diluted in ethanol and added to the retinal cell cultures at concentration of 0, 10  $\mu$ M, 20  $\mu$ M, and 40  $\mu$ M. Cultures are treated for 24 and 48 hours. A2E is obtained from Dr. Koji Nakanishi (Columbia University, New York City, NY) or is synthesized according to the method of Parish et al. (*Proc. Natl. Acad. Sci. USA* 95:14602-13 (1998)). An alkynyl phenyl derivative compound is then added to the culture. To other retinal cell cultures, an alkynyl phenyl derivative compound is added before application of the stressor or is added at the same time that A2E is added to the retinal cell culture. The cultures are maintained in tissue culture incubators for the

duration of the stress at 37 °C and 5% CO<sub>2</sub>. The cells are then analyzed by immunocytochemistry as described in Example 133.

#### Apoptosis Analysis

[001113] Retinal cell cultures are prepared as described in Example 195 and cultured for 2 weeks and then exposed to white light stress at 6000 lux for 24 hours followed by a 13-hour rest period. A device was built to uniformly deliver light of specified wavelengths to specified wells of the 24-well plates. The device contained a fluorescent cool white bulb (GE P/N FC12T9/CW) wired to an AC power supply. The bulb is mounted inside a standard tissue culture incubator. White light stress is applied by placing plates of cells directly underneath the fluorescent bulb. The CO<sub>2</sub> levels are maintained at 5%, and the temperature at the cell plate is maintained at 37 °C. The temperature was monitored by using thin thermocouples. The light intensities for all devices were measured and adjusted using a light meter from Extech Instruments Corporation (P/N 401025; Waltham, MA). An alkynyl phenyl-linked amine derivative compound is added to wells of the culture plates prior to exposure of the cells to white light and is added to other wells of the cultures after exposure to white light. To assess apoptosis, TUNEL is performed as described herein.

[001114] Apoptosis analysis is also performed after exposing retinal cells to blue light. Retinal cell cultures are cultured as described in Example 195. After culturing the cells for 1 week, a blue light stress is applied. Blue light is delivered by a custom-built light-source, which consists of two arrays of 24 (4X6) blue light-emitting diodes (Sunbrite LED P/N SSP-01TWB7UWB12), designed such that each LED is registered to a single well of a 24 well disposable plate. The first array is placed on top of a 24 well plate full of cells, while the second one is placed underneath the plate of cells, allowing both arrays to provide a light stress to the plate of cells simultaneously. The entire apparatus is placed inside a standard tissue culture incubator. The CO<sub>2</sub> levels are maintained at 5%, and the temperature at the cell plate is maintained at 37 °C. The temperature is monitored with thin thermocouples. Current to each LED is controlled individually by a separate potentiometer, allowing a uniform light output for all LEDs. Cell plates are exposed to 2000 lux of blue light stress for either 2 hours or 48 hours, followed by a 14-hour rest period. An alkynyl phenyl-linked amine derivative compound is added to wells of the culture plates prior to exposure of the cells to blue light and is added to other wells of the cultures after exposure to blue light. To assess apoptosis, TUNEL is performed as described herein.

[001115] To assess apoptosis, TUNEL is performed according to standard techniques practiced in the art and according to the manufacturer's instructions. Briefly, the retinal cell cultures are first fixed with 4% paraformaldehyde and then ethanol, and then rinsed in DPBS. The fixed cells are incubated with TdT enzyme (0.2 units/μl final concentration) in reaction buffer (Fermentas, Hanover, MD) combined with Chroma-Tide Alexa568-5-dUTP (0.1 μM final concentration) (Molecular Probes) for 1 hour at 37 °C. Cultures are rinsed with DPBS and incubated with primary antibody either overnight at 4° C or for 1 hour at 37 °C. The cells are then rinsed with DPBS, incubated with Alexa 488-conjugated secondary antibodies, and rinsed with DPBS. Nuclei are stained with DAPI, and the cultures are rinsed with DPBS before removing the glass coverslips and mounting them with Fluoromount-G on glass slides for viewing and analysis.

[001116] Cultures are analyzed by counting TUNEL-labeled nuclei using an Olympus IX81 or CZX41 microscope (Olympus, Tokyo, Japan). Twenty fields of view are counted per coverslip with a 20x objective lens. Six coverslips are analyzed by this method for each condition. Cells that are not exposed to an alkynyl phenyl derivative compound are counted, and cells exposed to the antibody are normalized to

the number of cells in the control. Data are analyzed using the unpaired Student's *t*-test.

#### EXAMPLE 197

##### IN VIVO LIGHT MOUSE MODEL

- [001117] This Example describes the effect of an alkynyl phenyl-linked amine derivative in an in vivo light damage mouse model.
- [001118] Exposure of the eye to intense white light can cause photo-damage to the retina. The extent of damage after light treatment can be evaluated by measuring cytoplasmic histone-associated-DNA-fragment (mono- and oligonucleosomes) content in the eye (*see, e.g., Wenzel et al., Prog. Retin. Eye Res.* 24:275-306 (2005)).
- [001119] Dark adapted male Balb/c (albino, 10/group) mice are gavaged with the Compounds of at various doses (0.03, 0.1, 0.3, 1, and 3 mg/kg) or vehicle only is administered. Six hours after dosing, the animals are subjected to light treatment (8,000 lux of white light for 1 hour). Mice are sacrificed after 40 hours of recovery in dark, and retinas are dissected. A cell death detection ELISA assay is performed according to the manufacturer's instructions (ROCHE APPLIED SCIENCE, Cell Death Detection ELISA plus Kit). Contents of fragmented DNA in the retinas are measured to estimate the retinal-protective activity of the compounds.

#### EXAMPLE 198

##### ELECTRORETINOGRAPHIC (ERG) STUDY

- [001120] This example describes determining the effect of an alkyne derivative compound that is a visual cycle modulator on the magnitude of the ERG response in the eyes of mice after oral dosing of the animals with the compound. The level of ERG response in the eyes is determined 18 and 66 hours after administering the compound to the animals.
- [001121] Three groups of nine-week old mice (19-25 grams), both genders (strain C5 7BL/6, Charles River Laboratories, Wilmington, MA) are housed at room temperature,  $72 \pm 4^\circ$  F, and relative humidity of approximately 25%. Animals are housed in a 12-hour light /dark cycle environment, have free access to feed and drinking water and are checked for general health and well-being prior to use and during the study. Body weights are determined for a representative sample of mice prior to initiation of dosing. The average weight determined from this sampling is used to establish the dose for all mice in the study.
- [001122] Each test compound is dissolved in the control solvent (EtOH), and diluted 1:10 (90ml/900ml) in corn oil (Crisco Pure Corn Oil, J.M. Smucker Company, Orrville, OH) to the desired dose (mg/kg) in the desired volume (~0.1 mL/animal). The control vehicle is ethanol:corn oil (1:10 (0.9ml/9ml)). The treatment designations and animal assignments are described in Table 16.

- [001123] Animals are dosed once orally by gavage, with the assigned vehicle control or test compounds during the light cycle (between 30min and 3 hours 30min after the beginning of the light cycle). The volume of the administered dose does not exceed 10 mL/kg.
- [001124] ERG recordings are made on dark-adapted and, subsequently (during the course of the same experiment), on light-adapted states. For the dark-adapted response, animals are housed in a dark-adapted environment for at least 1 hour prior to the recording, commencing at least 30 minutes after the start of the light cycle.
- [001125] At eighteen and sixty six hours after dosing, the mice were anesthetized with a mixture of Ketamine and Xylazine (100 mg/kg and 20 mg/kg, respectively) and placed on a heating pad to maintain stable core body temperature during the course of the experiment. Pupils were dilated by placing a 5 microliter drop of mydriatic solution (tropicamide 0.5%) in the recorded eye. A mouse corneal monopolar contact lens electrode (Mayo Corporation, Inazawa, Aichi, Japan) was placed on the cornea, and a subcutaneous reference low profile needle 12 mm electrode (Grass Telefactor, W Warwick, RI) was placed medial from the eye. A ground needle electrode was placed in the tail. Data collection was obtained using an Espion E<sup>2</sup> (Diagnosys LLC, Littleton, MA) ERG recording system with Color Dome Ganzfeld stimulator. Full dark-adapted intensity-response function was determined following a brief white flash stimuli of 14 intensities ranging from 0.0001 cd.s/m<sup>2</sup> to 333 cd.s/m<sup>2</sup>. Subsequently, full light-adapted intensity-response function was determined following a brief white flash stimuli of 9 intensities ranging from 0.33 cd.s/m<sup>2</sup> to 333 cd.s/m<sup>2</sup>. Analysis of the obtained responses was done off-line. Intensity-response function determination was done by fitting a sigmoid function to the data (Naka KI, Rushton WA, 1966; Naka KI, Rushton WA, 1967). ERG responses are summarized in Tables 17 and 18 below.

[001126] At 4 hours post-dose, dark-adapted ERG was suppressed in a dose-proportional manner by 2 doses (0.5 and 1mg/kg) of the compound. Both doses enhanced the maximal light-adapted ERG response. At 25 hours post dose, dark-adapted ERG increased significantly at 25 hours, remaining within < 20% of the vehicle-treated animals. The light-adapted ERG response remained enhanced.

[001127] A related example describes determining the effect of an alkyne derivative compound that is a visual cycle modulator on the level of ERG response in the eyes of mice after oral dosing of the animals with the compound. The experimental procedure is the same as that described in the previous example with the following exceptions: 12 to 16-week old BALB/c mice were used (body weights 16-25 g). [001128] The dosing resulted in a significant and dose-dependent (53%-96%) suppression of ERG dark-adapted intensity-response function for the 3 doses. This was accompanied by a relatively small (<15%)

increase in photopic  $V_{\max}$ .

#### EFFECT OF AN ALKYNYL PHENYL DERIVATIVE COMPOUND ON REDUCTION OF LIPOFUSCIN FLUOROPHORES

[001129] This Example describes the capability of an alkynyl phenyl derivative compound to reduce the level of existing A2E in the retina of mice as well as prevention of the formation of A2E.

[001130] The eyes of *abca4*-null (*abca4*  $-/-$ ) mutant mice (*see, e.g.*, Weng et al., *Cell* 98:13-23 (1999)) have an increased accumulation of lipofuscin fluorophores, such as A2E (*see, e.g.*, Karan et al., *Proc. Natl. Acad. Sci. USA* 102:4164-69 (2005)). Compounds (1 mg/kg) or vehicle are administered daily for three months by oral gavage to *abca4* $^{-/-}$  mice that are about 2 months old. Mice are sacrificed after three months of treatment. Retinas and RPE are extracted for A2E analysis.

[001131] A similar experiment is performed with aged balb/c mice (10 months old). The test mice are treated with 1 mg/kg/day of compounds for three months and the control mice are treated with vehicle

#### EFFECT OF AN ALKYNYL PHENYL DERIVATIVE COMPOUND ON RETINOID NUCLEAR RECEPTOR ACTIVITY

[001132] Retinoid nuclear receptor activity is associated with transduction of the non-visual physiologic, pharmacologic, and toxicologic retinoid signals that affect tissue and organ growth, development, differentiation, and homeostasis.

[001133] The effect of the Compound 4, Compound 28, and Compound 29 and the effect of a retinoic acid receptor (RAR) agonist (*E*-4-[2-(5,6,7,8-tetrahydro-5,5,8,8-tetramethyl-2-naphthylenyl)-1-propenyl] benzoic acid) (TTNPB), and of all-trans-retinoic acid (at-RA), which is an RAR and retinoid X receptor (RXR) agonist, were studied on RAR and RXR receptors essentially as described by Achkar et al. (*Proc. Natl. Acad. Sci. USA* 93:4879-84 (1996)). Results of these assays are presented in Table 6. Amounts as great as 10  $\mu$ M of each of Compound 4-HCl, Compound 28-HCl, and Compound 29-HCl did not show any significant effects on retinoid nuclear receptors (RAR and RXR). By comparison, TTNPB and at-RA activated the RXR $\alpha$ , RAR $\alpha$ , RAR $\beta$  and RAR $\gamma$  receptors as expected (Table 21).
