

**MANUALLY ADJUSTABLE CONVEYOR
BELT GUIDERAIL AND RELATED METHODS**

This application claims the benefit of U.S. Provisional Patent Application Ser. No. 62/861,633, filed June 14, 2019, and is also related to U.S. Provisional Patent Application Ser. No. 62/508,700, filed May 19, 2017, U.S. Provisional Patent Application Ser. No. 62/550,023, filed August 25, 2017, International Application Ser. No. PCT/US18/33665, filed May 21, 2018, and U.S. Patent Application Ser. No. 16/281,889, filed November 13, 2019, the disclosures of all of the foregoing applications are fully incorporated herein by reference.

Technical Field

[0001] This disclosure relates to the article conveying arts and, in particular, to a manually adjustable conveyor belt guiderail and related methods.

Background

[0002] Conveyors typically have rails positioned along each side of the conveyor chain or belt to guide an article along a conveying path. Articles travel between the rails, which are positioned to ensure that the articles remain on the conveying path. When a larger or smaller article is conveyed, or the width of the conveying path otherwise needs to be adjusted to accommodate an increased or reduced article flow, the guiderails must be adjusted to fit the situation.

[0003] Conventional guiderail adjustment systems use extending guide rods, which support a bracket attached to the guiderail. These guide rods also protrude outwardly away from the conveyor and into the surrounding area, thus increasing the overall width and footprint of the conveyor. The guiderails including rigid rods also create an

unappealing look, since the extended portions of the rods project from the conveyor sides. Some also require motorized adjustments, which can add to the cost and complexity.

[0004] Accordingly, a need is identified for an adjustable guiderail that overcomes the foregoing limitations and possibly others that have yet to be realized.

Summary

[0005] According to one aspect of the disclosure, an apparatus for supporting a guiderail for guiding one or more articles conveyed along a conveyor having a conveying path in a conveying direction. The apparatus comprises a support rail and at least one movable support for adjusting a position of the guiderail relative to the conveyor in a direction transverse to the conveying direction. The at least one movable support is adapted to engage the support rail, support the guiderail, and extend and retract relative to the conveying path in a direction transverse to the conveying direction to selectively position the guiderail relative to the support rail. The at least one movable support includes a clamp clamping the at least one movable support to the support rail for fixing a location of the movable support relative to the support rail.

[0006] In one embodiment, the at least one movable support includes a collapsible support comprising a pair of arms connected for pivoting movement relative to a shuttle for engaging the support rail. Each arm of the pair of arms is pivotably connected to a connector including a receiver adapted for receiving a portion of the guiderail. The connector includes an extension for engaging the support rail to prevent the pair of arms from reaching a locked position. At least one of the receivers comprises a retainer for engaging the support rail and/or at least one roller for rotatably engaging the support rail.

[0007] The clamp may comprise an actuator for selectively activating the clamp for engaging the support rail and releasing the clamp for allowing the movable support to slide along the support rail. The actuator may include a wedge for selectively engaging the support rail. The actuator may further comprise a lever. The at least one movable support may include a body including at least one retainer for retaining the actuator and an opening for receiving and retaining the wedge. The at least one retainer may be frictionally-

enhanced for engaging the actuator as a result of an opposing force created by engagement of the wedge with the support rail in an actuated condition of the actuator. The actuator may comprise a handle.

[0008] According to a further aspect of the disclosure, an apparatus for supporting a guiderail for guiding one or more articles conveyed along a conveyor having a conveying path in a conveying direction in connection with a support rail is provided. The apparatus comprises at least one movable support for adjusting a position of the guiderail relative to the conveyor in a direction transverse to the conveying direction. The at least one movable support includes a collapsible support for engaging the support rail and supporting the guiderail. The collapsible support is adapted to be extended and retracted into the conveying path in a direction transverse to the conveying direction to selectively position the guiderail relative to the support rail. The at least one movable support includes a clamp adapted to clamp the movable support to the support rail for fixing a location of the movable support relative to the support rail.

[0009] Still a further aspect of the disclosure relates to an apparatus for supporting a guiderail for guiding one or more articles conveyed along a conveyor having a conveying path in a conveying direction in connection with a support rail. The apparatus comprises a shuttle adapted for moving to and fro along the support rail. The shuttle includes a lever for selectively urging a retainer into engagement with the support rail to fix a location of the shuttle thereon.

[0010] In one embodiment, the retainer comprises a wedge. The apparatus may further include a collapsible support comprising a pair of arms connected for relative pivoting movement at one end. At least one of the arms is connected to the shuttle for engaging the support rail at another end. Each arm of the pair of arms may be pivotably connected to a connector, which includes a receiver adapted for receiving a portion of the guiderail. The connector includes an extension for engaging the support rail to prevent the pair of arms from reaching a locked position. The lever may comprise channels, each for engaging the retainer associated with the shuttle. Each retainer is frictionally-enhanced for

engaging the channels as a result of an opposing force created by the engagement of the retainer with the support rail in an actuated condition of the lever.

[0011] This disclosure also pertains to a method for adjustably supporting a guiderail for guiding one or more articles conveyed along a conveyor having a conveying path in a conveying direction. The method comprises clamping a movable support associated with the guiderail to a support rail. The method further comprises actuating the movable support to selectively extend or retract the guiderail toward or away from the conveying path.

[0012] The method may further include the step of releasing the clamp for allowing the movable support to slide along the support rail. The clamping step may comprise using a wedge to fix the position of the movable support. The clamping step may comprise lowering a clamp to form an engagement with the support rail, such as by pressing upwardly on a handle associated with the clamp.

[0013] Yet a further aspect of the disclosure pertains to a method of adjusting a guiderail for guiding one or more articles conveyed along a conveyor having a conveying path in a conveying direction. The method comprises manually engaging a first support for supporting the guiderail with a support rail to fix a position of the first support and hence the guiderail for guiding the one or more articles along the conveying path.

[0014] In one embodiment, the method further includes the step of manually engaging a second support for supporting the guiderail with the support rail. The method may further include the step of manually engaging third and fourth supports for supporting the guiderail with the support rail, wherein a first distance between the first and second supports along the support rail is different from a second distance between the third and fourth supports along the support rail.

Brief Description of the Drawing Figures

[0015] The accompanying drawing figures incorporated herein and forming a part of the specification, illustrate several aspects of the disclosed inventions and, together with the textual description, serve to explain certain principles thereof. In the drawing figures:

- [0016] Figure 1 is a top perspective view of one embodiment of a single conveyor guiderail adjuster according to one embodiment of the disclosure;
- [0017] Figure 2 is a bottom perspective view of the adjuster of Figure 1;
- [0018] Figures 3, 4, and 5, are top, rear, and bottom views of the adjuster of Figure 1;
- [0019] Figure 6 is a front view of the adjuster of Figure 1;
- [0020] Figures 7 and 8 are left-side and right-side views of the adjuster of Figure 1;
- [0021] Figure 9 is a perspective view of a collapsible guiderail support forming part of the adjuster of Figures 1-8;

- [0033] Figure 18 illustrates a tensioner for a cable forming part of the actuator for the adjustable support;

- [0034] Figures 19, 20, 21, 22 and 23 illustrate alternative forms of actuators;
- [0035] Figures 24, 25, and 26 illustrate a system comprising two opposed guiderails associated with a plurality of adjusters;
- [0036] Figures 27 and 28 illustrate various aspects of an extendable guiderail;
- [0037] Figure 31 and 32 illustrate guides for guiding an endless cable along a curved section of a support rail for the adjusters;
- [0038] Figures 32, 33, and 34 are schematic views illustrating the creation of various zones using the adjustable guiderails according to the disclosure; and
- [0039] Figures 35-42 illustrate an embodiment of a manually adjustable guiderail support.
- [0040] Reference will now be made in detail to the present preferred embodiments of a manually adjustable guiderail for a conveyor, examples of which are illustrated in the accompanying drawing figures.

Detailed Description

[0041] With reference to Figures 1-9, one possible embodiment of a guiderail adjuster 10 forming one aspect of the invention is illustrated. As illustrated, the adjuster 10 may be adapted to connect with a guiderail 12 for guiding articles along a conveying path and in a conveying direction D (see, e.g., Figure 19). The guiderail 12 may be supported by a support 14 forming a part of the adjuster 10, which may be flexible or collapsible (that is, able to be folded into a more compact shape). The adjuster 10 including the support 14 is thus capable of extending or retracting the guiderail 12 to change the relative position of the conveying path, without increasing the overall width of the associated conveyor in a transverse direction as a result of the adjustment.

[0042] In one embodiment, the support 14 may comprise links in the form of first and second supports or arms 16, 18 connected to each other. The arms 16, 18 are rigid in the vertical direction, but pivotally connected at their inner end portions, such as by a connector 20. The arms 16, 18 and connector 20 thus create a linkage (which may be in the form of a two bar linkage, but other forms could be used).

[0043] At the opposite end, each arm 16, 18 is connected to a structural part designed to reduce or eliminate friction or provide support or bearing. In the illustrated embodiment, this structure takes the form of a movable bolster or shuttle 22, 24 adapted to frictionally (by sliding or rolling) engage an elongated support rail 26, which extends generally parallel with the guiderail 12 in the conveying direction D. Consequently, these connections and the relative movement established allow for flexing or collapsing of the support 14 in a direction transverse to the conveying direction D.

[0044] The support 14 is also adapted to connect with the guiderail 12. In the illustrated embodiment, this is achieved by providing the connector 20 with one or more receivers, such as clips 20a, 20b (which as discussed in further detail below may provide engagement such that the guiderail 12 is fixed in position, or may be arranged to allow for relative sliding movement). As can be appreciated from Figure 6, the arrangement is such that the overall adjuster 10 has a very low vertical profile, with a height only slightly greater than the height of the guiderail 12. As can be seen in Figures 1-8, an optional cover 28 may also be provided (removed in Figure 9), which may engage the support rail 26 and provide a measure of protection for the movable parts of the adjuster 10, but without interfering with their relative movement and operation.

[0045] With reference to Figures 9 and 12, the nature of the pivoted connection of the arms 16, 18 forming the support 14 for the guiderail in one embodiment is shown. Each arm 16, 18 may be provided with a trunnion 16a, 18a, the ends of which are received and rotatably captured within upper and lower receivers 20c on either side of the connector 20. However, alternative configurations could be used, such as a simple hinge (with a mechanical pin or a living hinge). In any case, movement of the shuttles 22, 24 along the support rail 26 towards each other causes the connector 20, and hence, the associated guiderail (not shown) to move along an adjacent conveying surface in a direction transverse to the conveying direction. The movement is considered a flexible one, in that the pivoting of the arms 16, 18 relative to the connection allows flexing of the flexible joint thus formed. Likewise, movement of the shuttles 22, 24 in the opposite direction (farther away from

each other) causes the arms 16, 18 to flex relative to each other (and connector 20) and thereby retract the guiderail 12.

[0046] Allowing the arms 16, 18 forming the linkage to reach a “bottomed out” ($\beta=180$ degrees or more) and potentially locked position may be undesirable (especially when the actuation of the adjusters 10 is automated, as compared to manual). Thus, as can be appreciated from Figures 10 and 11, this condition may be avoided by providing the side of the connector 20 opposite the guiderail 12 with a protrusion or extension 20d projecting transverse to the conveying direction, which thus serves to define the maximum flexing of the joint formed between the arms 16, 18. This protrusion or extension 20d of the connector 20 may be sized and positioned to engage the support rail 26 in the fully collapsed position of the linkage, and thus prevent it from bottoming out and becoming locked in position. Of course, the protrusion could also be provided on one or both of the arms 16, 18, or even on the support rail 26, to achieve a similar result.

[0047] As can be appreciated with reference to Figures 10, 11, and 12, by way of being selectively extended or retracted, the support 14 creates an enhanced level of adjustability for an associated guiderail 12. The adjustments may be achieved in an easy and efficient manner, and without remarkably increasing the footprint of the overall conveyor system. Specifically, extending or retracting the support 14 allows the guiderail 12 pivotally attached thereto by virtue of connector 20 to be configured to provide a variable width conveying path for a number of differently sized articles to be conveyed. For example, when a smaller sized article is desired to be conveyed, the guiderail 12 need only be moved in an inward or inboard direction I transverse to the conveying direction D, thereby causing it to collapse in this direction (and thus causing the flexible joint to assume an acute angle α , such as for example as little as 5 degrees in the illustrated example, and possibly lower in the event the arms 16, 18 may be arranged parallel to each other)). In other words, the arms 16, 18 move from a position where the relative angle between them is greater to one in which it is reduced or smaller. This narrows the conveying path, and thus allows for a readily customizable arrangement for guiding a variety of differently sized articles.

[0048] Likewise, if it is desired to convey a larger sized article/object or otherwise extend the width of the conveying path relative to the underlying conveyor, the guiderail 12 need only be moved in an outward or outboard direction O transverse to the conveying direction D (and thereby flexing the joint so as to create a large, obtuse angle β between the arms 16, 18, which may be up to but not including 180 degrees, and as shown is limited by the presence of the extension or protrusion 20d to prevent a lock out condition). In other words, the arms 16, 18 move from a position where the relative angle between them is smaller to one in which it is greater. In all cases, it can be appreciated that no rod or like structure projecting outwardly from the support rail 26, and thus the overall width of the arrangement does not change as a result of the extension or retraction. The resulting conveyor system may thus have a smaller footprint than would otherwise be the case if transversely extending rods and corresponding mounts were utilized.

[0049] The adjustment of the support 14 may be manually or automatically done. In the manual version, and with reference to Figures 13 and 14, each shuttle 22, 24 may be provided with a retainer 30 for use in selectively engaging the support rail 26 and thereby holding the shuttle in the desired position. In the illustrated embodiment, the retainer 30 comprises a post 32 supporting an actuator in the form of a pivotally mounted lever 34, such as by way of snap-fit engagement with a clip 32a. The inside of the lever 34 includes a wedge 36, which is sized and positioned for not engaging the rail 26 in one position, but frictionally engaging it in a different position (note positions 34' (free) and 34'' in Figure 9 (retained)). Opposed plates 38, 40 may be retained by a fastener F to hold the post 32 in position, and each plate 38, 40 may include a guide 42 for slidably receiving a portion of the support rail 26. The plates 38, 40 may also include apertures 38a, 40a for receiving a corresponding fastener (such as a keyway plug 16c; see Figures 9A, 9B, and 9C) depending from a proximal end of each arm 16, 18 for pivotally connecting the ends of the arms 16, 18 with the shuttles 22, 24.

[0050] As can be appreciated, by disengaging the retainer 30 using lever 34, the associated shuttle 24 is free to move to and fro, such as by sliding, along the support rail 26, and thereby extend or retract the support 14 and, hence, the associated guiderail 12.

When a position is reached corresponding to the desired extension or retraction of the guiderail 12, the retainer 30 may be reactivated to establish fixed engagement with the support rail 26. As can be appreciated, it is only necessary to move one of the shuttles 22, 24 to achieve the desired extension or retraction of the guiderail 12 in view of the collapsible nature of the support 14 created by the pivotably connected arms 16, 18.

[0051] The shuttles 22, 24 may also be readily adapted to work in an automated environment. Specifically, at least one, and potentially each shuttle 22, 24 may be adapted to engage an actuator for causing movement to and fro along the support rail 26, depending on the degree of actuation, and thus extending or retracting the arms 16, 18. As shown in Figure 17, the actuator may comprise a connector for connecting with the shuttles 22, 24, such as a flexible cable 44. The cable 44 may extend over pulleys 46 at each end (only one shown in Figure 17 mounted to one end of the support rail 26, but the arrangement would essentially be the same as shown at the opposite end of the support rail 26; *see, e.g.*, Figure 19). The arrangement thus forms an endless loop (which may be associated with plural adjusters 10, as outlined further in the following description).

[0052] To cause the cable 44 to traverse the endless path, it may be entrained around a driver, such as capstan 48, which may be associated with a motor 50 (e.g., a servomotor) also forming part of the actuator in this embodiment. As shown in Figure 18, the cable 44 may also be provided with a tensioner, such as a turnbuckle 44a, to allow for the tension to be adjusted as necessary or desired.

[0053] In this example, and with reference to Figure 16, each plate 38, 40 may be provided with a retainer 52 for selectively engaging the cable 44. The retainer 52 may comprise a clamp in the form of a pivotable cam 54 (only upper one shown in Figure 16), but could take other forms as well (e.g., a bolt with a flange for capturing a portion of the cable 44 against a corresponding surface of the shuttle). The cam 54 may be journaled on a reduced diameter end 56a of a post 56, which may be held in place by a fastener F.

[0054] In the illustrated example, and with reference to Figures 16 and 16A, the cam 54 includes an enlarged, rounded inner face 54a for engaging and pressing the cable into engagement with a frictionally enhanced portion 55 of the plate 38, 40 (which may be

identical, but inverted; in other words, plate 38 is identical in form to plate 40 in Figure 16, so it can be understood that the upper plate includes frictionally enhanced portion 55), and a free end 54b adapted for tactile engagement for movement between the hold and release position. A lock, such as a removable locking tab 58 with flexible legs for engaging a projection 58a in a snap fit engagement, may also be provided for engaging and fixing the cam 54 in the locked or closed condition, thus engaging the cable (shown in phantom line in Figure 16A). A roller or pulley 60 may be rotatably journaled at the opposite, reduced diameter end 56b of post 56 (upper when the cam 54 is at the lower plate 38; lower when the cam 54 is at the upper plate 38, as shown in Figure 16).

[0055] As can be appreciated, the cable 44 has a forward run and a return run in view of the endless loop established. By connecting one shuttle 22 to the upper run using the clamp (cam 54) located as shown in Figure 16, and connecting the other shuttle 24 to the return run using a clamp (cam 54 on plate 40, as per Figure 16A) at a corresponding location, actuation using a single actuator thus causes the shuttles 22, 24 to move toward or away from each other, thereby flexing the joint of the support 14 created by arms 16, 18 and extending or retracting the guiderail 12. The alternate run of the cable 44 that is not fixed to the shuttle 22, 24 simply engages the roller/pulley 60, and thus does not impede the relative movement.

[0056] With continued reference to Figure 16, each shuttle 22, 24 may also be provided with rollers 62 to create low-friction engagement with the support rail 26. The rollers 62 may comprise individual rollers 62a connected to the plates 38, 40 by fasteners 64 and arranged for engaging an outer face of the support rail 26, as well as rollers 62b journaled in the plates 38, 40 for engaging the inside face of the support rail 26. As can be appreciated, the spaced rollers 62a allow for a portion of the rail 26 to pass for engaging and supporting the cover 28.

[0057] Alternative forms of actuation are possible, which advantageously may use a single actuator for activating plural adjusters 10 for adjusting the width of the conveying path. For example, as shown in Figure 19, the connector, such as cable 44, may be associated with a rack 66, which is arranged for engaging a rotatable pinion 68. In view of

the endless nature of the cable 44, and the corresponding connections with the shuttles 22, 24 as described above, actuation of the pinion 68 in one direction causes the simultaneous actuation of plural adjusters 10. This advances the guiderail 12 (shown as two disconnected portions with phantom portion for purposes of illustration) in the transverse direction T of the conveyor C (which as indicated has a conveying path P formed by a conveying surface (chain or belt B) in the conveying direction D, and note reduced width path P' as a result of the advance of the guiderail 12 in the transverse direction). Specifically, rotating the pinion in a clockwise direction moves the rack to the right in Figure 19, and in view of the connection of the forward run of the cable 44 with shuttles 22 of each guiderail adjuster 10, and the return run with shuttles 24, causes the advancement illustrated. Reversing the direction of rotation of pinion 68 causes the opposite movement to occur.

[0058] The actuation of the adjusters 10 associated with the conveyor C may again be manual or automated. Thus, as shown in Figures 20-22, a hand wheel 70 may be connected to the associated conveyor C and rotated to cause the actuation of one or more of the adjusters 10 (basically, as many as are connected to a single connector or cable 44, which could be any number (2, 5, 10, 20 or more), depending on the strength of the actuator arrangement used. Figure 23 illustrates the use of a motor 72 (e.g., servomotor) for automated operation.

[0059] Figures 24-26 illustrate an overview of a possible arrangement of the adjustable guiderail support system incorporating a plurality of adjusters 10 for use in connection with a conveyor having a conveying path (not shown). Opposed inner and outer guiderails 12a, 12b are shown for guiding articles (not shown) along the conveying path. The adjustable guiderail supports 14a, 14b are supporting inner guiderail 12a and the adjustable guiderail support 14c is supporting outer guiderail 12b. Thus, if it is desired adjust the conveying path width W to accommodate differently sized articles (or groups thereof), guiderail 12a (along with guiderail supports 14a, 14b) and guiderail 12b (along with guiderail support 14c and any others present) may be moved. The movement may again be manual or automatic using a single actuator (including cable 44) transverse the conveying direction D along each support rail 26 (with an associated motor, the operation

of which may be coordinated by a single controller) in order to widen or narrow the conveying path width W (note smaller width W' in Figure 25, and even smaller width W'' in Figure 26, which may correspond to a single row of articles being conveyed, such as bottles or cans). In such situations, it may be desirable to have the receivers (e.g., clips 20a, 20b) firmly engage the guiderail 12a, 12b at every other adjuster 10, but slidably engage at others, to allow for the desired extension and retraction.

[0060] Figures 27-28 illustrate that the guiderail 12 may comprise an extendable joint 74 comprised of portions, such as legs 12c, 12d, having a reduced vertical dimension (basically each equal to one half of the overall guiderail height). These legs 12c, 12d may overlie each other or overlap in a vertical direction, and are slidably received in receivers 76, which may take the form of C-shaped clamps that allow for relative movement of the legs (toward a common center during retraction of the guiderail 12 and away from it during extension). The receivers 76 thus retain the legs 12c, 12d together, yet capable of relative movement in the conveying direction during extension and retraction of the associated guiderail portions. This allows for the guiderail 12 to provide the desired extension and retraction, such as via supports 14, to accommodate a particular article being conveyed or form a particular conveying path. Hence, one or both of the legs 12c, 12d may be curved, but use of the supports 14 in connection with straight portions that are connected by the extendable joints is also possible. It can also be appreciated from Figure 28 that the extendable joints 74 allow for opposing guiderails 12 to extend or retract different amounts, which may occur when one is associated with an inside curve and the other with an outer curve.

[0061] Depending on the size or shape of the underlying conveyor C, it may also be desirable to provide a guide intermediate the adjusters 10 for guiding the connector, such as cable 44. As shown in Figures 29-31, this may be achieved using the manual shuttle 22 or 24 of Figures 13 and 14, which may be equipped with pulleys 60 for engaging the upper and lower runs of the cable 44. The shuttles 22, 24 may be selectively positioned using the associated retainers 30. Stationary brackets 78 may also be provided with upper and lower guides 78a, 78b for guiding the respective runs of the cable 44.

[0062] Figures 32-34 schematically illustrate a possible application of the adjusters 10 to create zones of different widths in a single conveyor or conveyor system (e.g., comprised of multiple conveyors). As shown in Figure 32, a first series of adjusters 10a associated with an underlying conveyor C may be used to provide an upstream portion of the conveyor with guiderails 12a, 12b spaced farther apart, thus forming a first zone Z1, and a second series of adjusters 10b may be used to place downstream guiderails 12e, 12f spaced closer together, thus forming a second zone Z2. The adjusters 10a, 10b may be manually adjusted, or associated with different actuators (e.g., a cable system, as described above). Later in time, as indicated in Figure 33, the adjusters 10a, 10b may be altered to make the zones Z1, Z2 the same width, or for zone Z2 to be wider than zone Z1, as indicated in Figure 34. As can be appreciated, the material of the guiderails 12a-12b may be flexible or include flexible interconnections (including the joints 74 described above) to allow for the relative movement, which is exaggerated in the schematic figures for purposes of illustration).

[0063] An alternate embodiment of an adjuster in the form of a movable support 100 adapted for being manually adjusted is described with reference to Figures 35-42. From Figures 34, 35, and 36, it can be understood that each movable support 100 comprises a connector in the form of a shuttle 102 for engaging a stationary support rail 104, and which is connected to a guiderail support arm 106. The shuttle 102 includes a body 108 including a pair of retainers 110 for supporting a clamp 112. The clamp 112 comprises an actuator in the form of a lever 114 adapted for moving along the retainers 110, such as in a vertical direction. Movement of the lever 114 forces a movable retainer, such as a wedge 116 into engagement with the corresponding (outer) surface of the support rail 104 (compare position of lever 114 and wedge 116 in Figure 38 with raised position of lever 114' and wedge 116' in Figure 39 for engaging the support rail (not shown) that would be present in opening Q).

[0064] The lever 114 may include a receiver 114a for receiving the wedge 116 and urging it into engagement with the support rail 104 as the lever is moved, such as in a vertical direction. The lever 114 may further channels 114b for receiving the retainers 110,

which may be frictionally enhanced (such as by including threading, as shown), to create a suitable retention force and hold the lever 114 in the actuated condition as a result of the outwardly directed force created by wedge 116, yet be easily releasable using finger action (note handle 114c for this purpose; that is, moving the lever 114 upwardly to force the wedge 116 into engagement with the support rail).

[0065] As indicated previously, a movable support 100 may be associated with each support arm, including a second support arm 118, as shown in Figure 40. This movable support 100 need not include any retainer for fixing its position along the support rail, since it is connected by way of arms 106, 118 to the fixable support described above. This second support 100 may include one or more rollers 120 for facilitating low-friction rolling contact with the support rail (not shown), which would be located in opening Q. However, as indicated in Figure 41, it is possible to provide each support 100 with a clamp 112, which may be used to independently fix it to the associated support rail 104.

[0066] As can be understood with reference to Figure 42, the above-described embodiment allows for each support 100 to be independently moved along the support rail 104 to a position (such as closer to each other or further apart from each other in the conveying direction) for positioning a guiderail connector, illustrated in the form of a receiver 124, associated with the respective support arms 106, 118 (which connector 124 may include an extension 124a for engaging the support rail 104 in a collapsed condition of the support 100 to prevent it from bottoming out). In this manner, the relative positioning of the guiderail (not shown) may be independently and selectively adjusted by a user, and using a manual approach that avoids the need for power, motors, etc. Yet, the low-profile nature of the supports 100 is retained, which allows for a conveyor system to be provided which lacks the outwardly directed rods or like structures that can create various problems, as noted above.

[0067] Summarizing, this disclosure may be considered to relate to the following items in any combination:

1. An apparatus for supporting a guiderail for guiding one or more articles conveyed along a conveyor having a conveying path in a conveying direction, comprising:

a support rail; and

at least one movable support for adjusting a position of the guiderail relative to the conveyor in a direction transverse to the conveying direction including a clamp for clamping to the support rail for fixing a location of the at least one movable support relative to the support rail.

2. The apparatus of item 1, wherein the at least one movable support includes a collapsible support comprising a pair of arms connected for pivoting movement relative to a shuttle for engaging the support rail.

3. The apparatus of item 2, wherein each arm of the pair of arms is pivotably connected to a connector, the connector including a receiver adapted for receiving a portion of the guiderail.

4. The apparatus of item 3, wherein the connector includes an extension for engaging the support rail to prevent the pair of arms from reaching a locked position.

5. The apparatus of any of items 1-4, wherein the at least one movable support comprises a retainer for engaging the support rail.

6. The apparatus of any of claims 1-5, wherein the at least one movable support includes at least one roller for rotatably engaging the support rail.

7. The apparatus of any of items 1-6, wherein the clamp comprises an actuator for selectively activating the clamp for engaging the support rail and releasing the clamp for allowing the at least one movable support to slide along the support rail.

8. The apparatus of item 7, wherein the actuator includes a wedge for selectively engaging the support rail.

9. The apparatus of item 7 or item 8 wherein the actuator comprises a lever.

10. The apparatus of any of items 1-9, wherein the at least one movable support comprises a body including at least one retainer for retaining the actuator and an opening for receiving and retaining the wedge.

11. The apparatus of item 10, wherein the at least one retainer is frictionally-enhanced for engaging the actuator as a result of an opposing force created by engagement of the wedge with the support rail in an actuated condition of the actuator.

12. The apparatus of any of items 8-11, wherein the actuator comprises a handle.

13. An apparatus for supporting a guiderail for guiding one or more articles conveyed along a conveyor having a conveying path in a conveying direction in connection with a support rail, comprising:

at least one movable support for adjusting a position of the guiderail relative to the conveyor in a direction transverse to the conveying direction, the at least one movable support comprising a collapsible support for engaging the support rail and supporting the guiderail, the collapsible support adapted to extend and retract into the conveying path in a direction transverse to the conveying direction to selectively position the guiderail relative to the support rail, the at least one movable support including a clamp adapted to clamp the at least one movable support to the support rail for fixing a location of the at least one movable support relative to the support rail.

14. An apparatus for supporting a guiderail for guiding one or more articles conveyed along a conveyor having a conveying path in a conveying direction in connection with a support rail, comprising:

a shuttle adapted for moving to and fro along the support rail, the shuttle including a lever for selectively urging a retainer into engagement with the support rail to fix a location of the shuttle thereon.

15. The apparatus of item 14, wherein the retainer comprises a wedge.

16. The apparatus of item 14 or item 15, further including a collapsible support comprising a pair of arms connected for relative pivoting movement at one end, and at least one of the arms connected to the shuttle for engaging the support rail at another end.

17. The apparatus of item 16, wherein each arm of the pair of arms is pivotably connected to a connector, the connector including a receiver adapted for receiving a portion of the guiderail.

18. The apparatus of item 17, wherein the connector includes an extension for engaging the support rail to prevent the pair of arms from reaching a locked position.

19. The apparatus of any of items 14-18, wherein the lever comprises channels, each for engaging the retainer associated with the shuttle.

20. The apparatus of item 19, wherein each retainer is frictionally-enhanced for engaging the channels as a result of an opposing force created by the engagement of the retainer with the support rail in an actuated condition of the lever.

21. A method for adjustably supporting a guiderail for guiding one or more articles conveyed along a conveyor having a conveying path in a conveying direction, comprising:

clamping a movable support associated with the guiderail to a support rail;

and

actuating the movable support to selectively extend or retract the guiderail toward or away from the conveying path.

22. The method of item 21, further including the step of releasing the clamp for allowing the movable support to slide along the support rail.

23. The method of item 21, wherein the clamping step comprises using a wedge to fix the position of the movable support.

24. The method of item 21, wherein the clamping step comprises lowering a clamp to form an engagement with the support rail.

25. The method of item 24, wherein the clamping step comprises pressing upwardly on a handle associated with the clamp.

26. A method of adjusting a guiderail for guiding one or more articles conveyed along a conveyor having a conveying path in a conveying direction, comprising:

manually engaging a first support for supporting the guiderail with a support rail to fix a position of the first support and hence the guiderail for guiding the one or more articles along the conveying path.

27. The method of item 26, further including the step of manually engaging a second support for supporting the guiderail with the support rail.

28. The method of item 27, further including the step of manually engaging third and fourth supports for supporting the guiderail with the support rail, wherein a first distance between the first and second supports along the support rail is different from a second distance between the third and fourth supports along the support rail.

[0068] The foregoing descriptions of various embodiments of a manually adjustable guiderail and related methods provide illustration of the inventive concepts. The descriptions are not intended to be exhaustive or to limit the disclosed invention to the precise form disclosed. Modifications or variations are also possible in light of the above teachings. For instance, the connector forming a part of the actuator may comprise a flexible ribbon, which may be manually actuated by a lever or similar projecting piece by which a mechanism is operated or adjusted. While the shuttles 22, 24 are shown as overlying and sliding upon the support rail 26, the shuttles could also be recessed within cavities in the support rail 26, while still functioning as shuttles. The shuttles may also take different forms, such as for example elongated flexible ribbons connected to the arms 16, 18 and designed to move along the support rail 26 or within a cavity formed therein. Any elements described herein as singular can be pluralized (i.e., anything described as “one” can be more than one), and plural elements can be used individually. Characteristics disclosed of a single variation of an element, the device, the methods, or combinations thereof can be used or apply for other variations, for example, dimensions, shapes, materials, or combinations thereof. The terms “generally,” “substantially,” “about,” or “approximately” are meant to mean as close to the corresponding condition as reasonably possible, and typically not varying from it by more than 10%, unless circumstances indicate otherwise. Any species element of a genus element can have the characteristics or elements of any other species element of that genus. The term “comprising” is not meant to be limiting. The above-described configurations, elements or complete assemblies and methods and their elements for carrying out the invention, and variations of aspects of the invention can be combined and modified with each other in any combination.
