

Description

The present invention relates to a coffee brewing apparatus comprising a filter chamber for brewing coffee, a water tank, a heater for heating water delivered from the water tank and providing hot water to the filter chamber, and a main power supply switch.

A coffee brewing apparatus provided with a mill to grind coffee beans is known, and that kind of apparatus with a timer is disclosed in Japanese Utility Model Publication No. 615215. The operation of this apparatus will be explained with reference to Figure 3.

The current time and desired activation time are set by means of a fast-traverse button 34 or a slow-traverse button 35 together with a time setting button 36. Then, when a main switch 37 is toggled from "OFF" position to "TIMER" position, the coffee brewing apparatus gets into the timer mode. If a mill switch is depressed during the timer mode, mill 28 is energized causing coffee beans to be ground resulting in coffee powder. When the current time coincides with the activation time, power is supplied to a heater and water contained in water tank 27 is heated. Coffee beverage is brewed by transmitting hot water through the coffee powder ground by mill 28. The brewed coffee is poured into the coffee vessel 31 from upper protrusion 29. Then, a heating plate contained in base 30 keeps the coffee warm.

However, the coffee taste worsens due to oxidization if the coffee is warmed for a long time. Therefore, the known coffee brewing apparatus automatically ceases to supply power to the heating plate following the operation of the timer of the apparatus if a predetermined time (59 minutes) lapses after brewing.

The main switch employed in the known coffee brewing apparatus is a dual three-contact switch which can take three positions: "TIMER", "OFF" or "ON". While the switch is in the "ON" position, power is always supplied to the heater. If the switch is turned to the "OFF" position, the power source is switched off.

In addition to this kind of a dual three-contact switch, a tumbler switch, a push-button switch or a switch having a timer function realized by a spiral spring, are conventionally utilized as a power switch of the coffee brewing apparatus. However, in case such a switch is employed the power source has to be turned off by hand.

Generally, a thermostat is arranged between the heater and the power lines in order to keep the heater temperature within a limited range. The circuit is turned on by this thermostat if the temperature falls below a preselected temperature, for example 90°C, and is turned off if it rises above another preselected temperature, for example 120°C. Furthermore, the coffee brewing apparatus is generally provided with a thermal fuse near the heater in order to prevent the situation in which the thermostat does not turn off the heater even if the temperature rises above the preselected maximum temperature and the heater continues to be heated.

In the coffee brewing apparatus shown in the above-mentioned Utility Model Publication No. 61-5215, the power to the heater is automatically cut-off by a timer after a predetermined time elapses. In a conventional coffee brewing apparatus, when a heating plate is heated excessively, the melting of a thermal fuse cuts-off the power supply to the heater. However, in the case of the known apparatus, power continues to be supplied to the electric portion of the apparatus other than the heater portion so that the electrical portion still might cause a fire. Therefore, in the known coffee brewing apparatus, each time that power is no longer supplied to the heater, or each time that an abnormal situation happens, the user must turn off the power switch manually in order to remove the possibility of having a fire.

Furthermore in the known apparatus, if a motor is heated abnormally or excessively due to overload and the operator does not recognize the abnormal situation, the motor will be burned out.

It is one of the objects of the present invention to provide a coffee brewing apparatus having a greater safety than a conventional apparatus. The invention solves the above-mentioned problems of the prior art by providing a coffee brewing apparatus with a main power supply switch having a switch function by which an "on"-state and an "off"-state are alternately selected in response to a manual operation of said main power supply switch characterized in that means to release said "on"-state in response to a releasing signal is provided. When a motor or a heater in the coffee brewing apparatus becomes abnormal, or when it is unnecessary to supply power to a heating plate when a definite time has elapsed after finishing the brewing, the releasing signal from an electronic circuit automatically cuts off the whole apparatus.

Figure 1 shows the first working example of the present invention, a circuit diagram of a coffee brewing apparatus with a mill.

Figure 2 shows a circuit diagram of a coffee brewing apparatus being a second working example of the present invention.

Figure 3 is a perspective view of a known coffee brewing apparatus with a mill.

The first working example of the invention exemplified on a coffee brewing apparatus with a mill will be explained with reference to Figure 1.

The coffee brewing apparatus comprises the same filter chamber water tank and hot water providing apparatus as the known one.

The series combination of a resistor and an indicator lamp 6 for signaling that the power is on, the series combination of a thermostat 7, a thermal fuse 43, a heater 8, for example combined with a heating plate and relay contacts 9 for the heater, and the series combination of a motor 10 and relay contacts 11 for the motor, are connected in parallel to the power lines leading from power introduction plug 1. A main power supply switch 2 is arranged in one or both of the power lines.

In the same way as a conventional push-button switch, the power switch 2 alternates between the locked states "ON" and "OFF" each time that switching button 3 is depressed. If a releasing signal is applied, solenoid 5 is excited and moves the "on"-state releasing lever 4. In this way the locked "on"-state of switch 2 is released, and the switch 2 switches to its "off"-state.

In addition, transformer 14, rectifying diodes 15 and three-terminal regulator 16 are also connected to the power lines. This circuit configuration generates a 5 volt direct voltage which is supplied to the power source terminal of a microprocessor 24.

A signal line 12 from a temperature sensor (not shown) such as a thermistor provided near the heater and heating plate 8, and a signal line 13 from another temperature sensor (not shown), provided near the motor 10 are connected to a multiplexer 17.

The output of the multiplexer 17 is applied to the microprocessor 24 via a sampling-hold circuit 18 and an analog-to-digital converter 19.

A relay 20 for the motor and a relay 21 for the heater are connected, through transistors, to a direct voltage source of 5V and also to microprocessor 24.

Furthermore, the microprocessor 24 is connected with the LED group 22 to indicate the system state, to the input buttons 23 for directing the coffee brewing apparatus and to the quartz oscillator 25 for clock pulses. The microprocessor may be reset by means of a circuit 26 when the power is switched on.

Now, the operation of the first working example of the coffee brewing apparatus with a coffee mill according to the invention will be explained.

If heater 8 with combined heating plate is overheated due to the breakdown, for example, of the thermostat, the thermistor arranged near the heater 8 detects the overheating and then generates a signal. The signal indicating the abnormal state is transmitted to microprocessor 24 via signal line 12. In response to the signal, microprocessor 24 sends a pulse signal for releasing the "on"-state via a transistor, to the solenoid 5 of main powder supply switch 2. In response to the pulse signal, solenoid 5 is excited and moves the "on"-state releasing lever 4. Thus the locked "on"-state of main power supply switch 2 is released and all parts of the coffee brewing apparatus are turned off from the power source.

In a second mode of operation of the safety switch, if motor 10 is overheated during coffee beans being ground, a signal to indicate the abnormal condition is sent to microprocessor 24 via the signal line 13 from the thermistor arranged near motor 10. Depending on this signal, microprocessor 24 transmits a releasing signal to main power supply switch 2 to switch off the coffee brewing apparatus.

When the brewing has finished, the brewed coffee is kept warm by the heating plate for a predetermined period of time. When this time period has elapsed, microprocessor 24 sends a releasing signal to main power supply switch 2 in order to prevent degrading of the coffee taste. Thus the coffee brewing apparatus is turned off completely and the keep-hot process for coffee finishes.

Next, referring to Figure 2, the second working example of the present invention will be explained. The coffee brewing apparatus in this example does not comprise a coffee mill. The same function as that of the first working example is realized not by means of the microprocessor as in the first working example, which is expensive, but by means of discrete devices.

Depressing the switching button 3 of main power supply switch 2, which is similar to that used in the first example, realizes the "on"-state. A current is provided to heater 8 via thermostat 7 to start pumping. If a predetermined amount of pumping has finished, the temperature of heater 8 rises rapidly. When it reaches the predetermined temperature, for example 115°C, thermostat 7 is turned off. Reset/timer-starting control circuit 39 detects the above state through a photo-coupler 38, and makes timer 40 start.

Timer 40 (HEF 4060) generates one pulse after every interval of, for example, 15 minutes. In response to the pulse, a shift register 41 turns off one LED of LED group 22 for each interval. In the initial state all LEDs of LED group 22 were turned on.

After a predetermined fixed period of time has elapsed, shift register 41 generates a pulse which turns off the last LED and which at the same time is sent to power switch 2 via transistors Q₁ and Q₂, causing lever 4 to be moved and switching of the apparatus.

If the heater is overheated and exceeds a predetermined temperature, for example 200°C, a signal detected by a thermistor is sent to the abnormal temperature detecting circuit 42 via signal line 12. The abnormal temperature detecting circuit 42 sends a releasing signal to main power supply switch 2, causing the coffee brewing apparatus to be turned off.

In order to keep the coffee temperature at a desired temperature, after pumping has finished, thermostat 7 repeats on-and-off operation until the power source is switched off. Therefore, reset/timer-starting circuit 40 is arranged not to receive any signals after starting the timer by receiving the first signal from photo coupler 38.

5 The following effects can be expected for the coffee brewing apparatus of the invention:

(1) When the heater portion of the coffee brewing apparatus is overheated, not only the heater but also the power source itself is automatically disabled, which results in a noteworthy improved safety of the apparatus.

10 (2) Even if the abnormal condition occurs in the motor, the power source is switched off to cease the working of the motor, so that the motor does not burn out as does the motor in the known apparatus.

(3) When the process of keeping coffee hot finishes after a predetermined period of time has elapsed, not only the heater but also any other portion is turned off, whereby the possibility of having a fire can be completely removed, and also saving of electricity can be attained.

15 (4) It is unnecessary to turn off the main power supply switch manually each time that the heating process of the coffee finishes or an abnormal situation has occurred.

Claims

1. A coffee brewing apparatus comprising a filter chamber for brewing coffee, a water tank (27), a heater (8) for heating water delivered from the water tank (27) and providing hot water to the filter chamber, and a main power supply switch (2) having a switch function by which an "on"-state and an "off"-state are alternately selected in response to a manual operation (3) of said main power supply switch, characterized in that means (4,6) to release said "on"-state in response to a releasing signal is provided.
2. A coffee brewing apparatus as claimed in Claim 1, characterized in that detecting means are provided for detecting an abnormal situation, and the releasing signal is a signal (12,13) generated by said detecting means in response to a detected abnormal situation.
3. A coffee brewing apparatus as claimed in Claim 1, characterized in that the releasing signal is a signal generated when a predetermined fixed period of time has elapsed. (24,25)
4. A coffee brewing apparatus as claimed in Claim 1, characterized in that detecting means are provided for detecting an abnormal situation and that the releasing signal comprises a signal (12,13) generated by said detecting means and a signal generated when a predetermined fixed period of time has elapsed. (24,25)
5. A coffee brewing apparatus as claimed in any of the Claims 1 to 4, characterized by that the coffee brewing apparatus comprises a coffee mill (28).

Patentansprüche

1. Kaffeemaschine mit einer Filterkammer zum Kochen von Kaffee, einem Wasserbehälter (27), einer Heizvorrichtung (8) zum Erhitzen von von dem Wasserbehälter geliefertem Wasser und zum Versorgen der Filterkammer mit heißem Wasser sowie einem Hauptstromschalter (2) mit einer Schaltfunktion, mit dem ein "EIN"-Zustand und ein "AUS"-Zustand als Reaktion auf eine manuelle Betätigung (3) des Hauptstromschalters abwechselnd gewählt werden, dadurch gekennzeichnet, daß Mittel (4, 5) zum Aufheben des "EIN"-Zustands als Reaktion auf ein Entriegelungssignal vorhanden sind.
2. Kaffeemaschine nach Anspruch 1, dadurch gekennzeichnet, daß Detektionsmittel zur Detektion einer anormalen Situation vorhanden sind und das Entriegelungssignal ein von diesen Detektionsmitteln als Reaktion auf eine detektierte anormale Situation erzeugtes Signal (12, 13) ist.
3. Kaffeemaschine nach Anspruch 1, dadurch gekennzeichnet, daß das Entriegelungssignal ein nach Ablauf einer vorgegebenen festen Zeitdauer erzeugtes Signal ist. (24, 25)
4. Kaffeemaschine nach Anspruch 1, dadurch gekennzeichnet, daß Detektionsmittel zur Detektion einer anormalen Situation vorhanden sind und daß das Entriegelungssignal ein von den Detektionsmitteln erzeugtes Signal (12, 13) und ein nach Ablauf einer vorgegebenen festen Zeitdauer erzeugtes Signal (24, 25) umfaßt.
5. Kaffeemaschine nach einem der Ansprüche 1 bis 4, dadurch gekennzeichnet, daß die Kaffeemaschine eine Kaffeemühle (28) umfaßt.

Revendications

1. Percolateur comprenant une chambre à filtre pour infuser du café, un réservoir d'eau (27), un élément chauffant (8) pour chauffer de l'eau provenant du réservoir d'eau (27) et pour fournir de l'eau chaude à la chambre à filtre, et un interrupteur d'alimentation électrique principal (2) présentant une fonction d'interrupteur par laquelle un état "MARCHE" et un état "ARRET" sont alternativement sélectionnés en réponse à un actionnement manuel (3) de l'interrupteur d'alimentation électrique principal, caractérisé en ce qu'un moyen (4, 5) destiné à déclencher l'état "MARCHE" en réponse à un signal de déclenchement est prévu.

2. Percolateur suivant la revendication 1, caractérisé en ce que des moyens de détection sont prévus pour détecter une situation anormale, et le signal de déclenchement est un signal (12, 13) engendré par les moyens de détection en réaction à une situation anormale détectée.
- 5 3. Percolateur suivant la revendication 1, caractérisé en ce que le signal de déclenchement est un signal engendré au terme d'une période de temps fixe prédéterminée (24, 25).
- 10 4. Percolateur suivant la revendication 1, caractérisé en ce que des moyens de détection sont prévus pour détecter une situation anormale et que le signal de déclenchement comprend un signal (12, 13) engendré par les moyens de détection et un signal engendré au terme d'une période de temps fixe prédéterminée (24, 25).
- 15 5. Percolateur suivant l'une quelconque des revendications 1 à 4, caractérisé en ce qu'il comprend un moulin à café (28).
