

DOWNHOLE JOINT ASSEMBLY FOR FLOW CONTROL, AND METHOD FOR COMPLETING A WELLBORE

STATEMENT OF RELATED APPLICATIONS

[0001] This application claims the benefit of U.S. Provisional Pat. Appl. No. 61/719,274 filed October 26, 2012, and U.S. Provisional Pat. Appl. No. 61/878,461 filed September 16, 2013, and both are incorporated by reference herein in their entirety.

BACKGROUND OF THE INVENTION

[0002] This section is intended to introduce various aspects of the art, which may be associated with exemplary embodiments of the present disclosure. This discussion is believed to assist in providing a framework to facilitate a better understanding of particular aspects of the present disclosure. Accordingly, it should be understood that this section should be read in this light, and not necessarily as admissions of prior art.

Field of the Invention

[0003] The present disclosure relates to the field of well completions. More specifically, the present invention relates to the isolation of formations in connection with wellbores that have been completed through multiple zones. The application also relates to a wellbore completion apparatus which incorporates bypass technology but which allows for the control of fluids through primary and secondary flow paths along the wellbore.

Discussion of Technology

[0004] In the drilling of oil and gas wells, a wellbore is formed using a drill bit that is urged downwardly at a lower end of a drill string. After drilling to a predetermined depth, the drill string and bit are removed and the wellbore is lined with a string of casing. An annular area is thus formed between the string of casing and the formation. A cementing operation is typically conducted in order to fill or “squeeze” the annular area with cement. The combination of cement and casing strengthens the wellbore and facilitates the isolation of formations behind the casing.

[0005] It is common to place several strings of casing having progressively smaller outer diameters into the wellbore. The process of drilling and then cementing progressively smaller strings of casing is repeated several times until the well has reached total depth. The final string of casing, referred to as a production casing, is cemented in place and perforated. In some instances, the final string of casing is a liner, that is, a string of casing that is not tied back to the surface.

[0006] As part of the completion process, a wellhead is installed at the surface. The wellhead controls the flow of production fluids to the surface, or the injection of fluids into the wellbore. Fluid gathering and processing equipment such as pipes, valves and separators are also provided. Production operations may then commence.

[0007] It is sometimes desirable to leave the bottom portion of a wellbore open. In open-hole completions, a production casing is not extended through the producing zones and perforated; rather, the producing zones are left uncased, or “open.” A production string or “tubing” is then positioned inside the open wellbore extending down below the last string of casing.

[0008] There are certain advantages to open-hole completions versus cased-hole completions. First, because open-hole completions have no perforation tunnels, formation fluids can converge on the wellbore radially 360 degrees. This has the benefit of eliminating the additional pressure drop associated with converging radial flow and then linear flow through particle-filled perforation tunnels. The reduced pressure drop associated with an open-hole completion virtually guarantees that it will be more productive than an unstimulated, cased hole in the same formation.

[0009] Second, open-hole techniques are oftentimes less expensive than cased hole completions. For example, the use of gravel packs eliminates the need for cementing, perforating, and post-perforation clean-up operations. Alternatively, the use of a perforated base pipe along the open hole wellbore helps maintain the integrity of the wellbore while allowing substantially 360 degree radial formation exposure.

[0010] It is desirable in some open-hole completions to isolate selected zones along the wellbore. For example, it is sometimes desirable to isolate an interval from the production of formation fluids into the wellbore. Annular zonal isolation may also be desired for production allocation, production/injection fluid profile control, selective stimulation, or gas control. This may be done through the use of packers (or a zonal isolation apparatus) that has bypass technology. The bypass technology may employ fluid transport conduits that permit fluids to flow through a sealing element of the packer and across an isolated zone.

[0011] The use of bypass technology with a zonal isolation apparatus has been developed in the context of gravel packing. This technology is practiced under the name Alternate Path[®]. Alternate Path[®] technology employs shunt tubes, or alternate flow channels, that allow a gravel slurry to bypass selected areas, e.g., premature sand bridges or packers, along a wellbore. Such fluid bypass technology is described, for example, in U.S. Pat. No. 5,588,487 and U.S. Pat. No. 7,938,184. Additional references which discuss alternate flow channel

technology include U.S. Pat. No. 8,215,406; U.S. Pat. No. 8,186,429; U.S. Pat. No. 8,127,831; U.S. Pat. No. 8,011,437; U.S. Pat. No. 7,971,642; U.S. Pat. No. 7,938,184; U.S. Pat. No. 7,661,476; U.S. Pat. No. 5,113,935; U.S. Pat. No. 4,945,991; U.S. Pat. Publ. No. 2012/0217010; U.S. Pat. Publ. No. 2009/0294128; M.T. Hecker, *et al.*, “Extending Openhole Gravel-Packing Capability: Initial Field Installation of Internal Shunt Alternate Path Technology,” SPE Annual Technical Conference and Exhibition, SPE Paper No. 135,102 (September 2010); and M.D. Barry, *et al.*, “Open-hole Gravel Packing with Zonal Isolation,” SPE Paper No. 110,460 (November 2007). The Alternate Path[®] technology enables a true zonal isolation in multi-zone, openhole gravel pack completions.

[0012] In some open-hole completions, a gravel pack is not employed. This may be due to the formation being sufficiently consolidated that a sand screen and pack are not required. Alternatively, this may be due to economic limitations. In either instance, it is still desirable to run tubular bodies down the wellbore to support packers or other tools, and to provide flow control between a main base pipe and the annulus formed between the base pipe and the surrounding wellbore.

[0013] Therefore, a need exists for a joint assembly that provides flow control between a base pipe and a surrounding annular region using fluid bypass technology. This may be for the production of formation fluids, the injection of fluids into a formation, or for the placement of wellbore treatment fluids along a formation. A need further exists for a downhole flow control system that provides for fluid communication between a primary flow path within a base pipe and the alternate flow path of fluid transport conduits. Additionally, a need exists for a method of completing a wellbore wherein a joint assembly is placed along an open hole formation that uses selected fluid communication between the base pipe and bypass channels.

SUMMARY OF THE INVENTION

[0014] A joint assembly is first provided herein. The joint assembly resides within a wellbore. The joint assembly has particular utility in connection with the control of fluid flow between an internal bore of a base pipe and an annular region outside of the base pipe, all residing within a surrounding open-hole portion of the wellbore. The open-hole portion extends through one, two, or more subsurface intervals.

[0015] The joint assembly includes a first base pipe and a second base pipe. The two base pipes are connected in series. Each base pipe comprises a tubular body. The tubular bodies each have a first end, a second end and a bore defined there between. The bores form a primary flow path for fluids.

[0016] The joint assembly preferably also includes a load sleeve and a torque sleeve. The load sleeve is mechanically connected proximate to the first end of the second base pipe, while the torque sleeve is mechanically connected proximate to the second end of the first base pipe. The load sleeve and the torque sleeve, in turn, are connected by means of a coupling joint. Preferably, the load sleeve and the torque sleeve are bolted into the respective base pipes to prevent relative rotational movement.

[0017] Each of the load sleeve and the torque sleeve comprises an elongated cylindrical body. The sleeves each have an outer diameter, a first and second end, and a bore extending from the first end to the second end. The bore forms an inner diameter in each of the elongated bodies. Each of the load sleeve and the torque sleeve also includes at least one transport conduit, with each of the transport conduits extending through the respective sleeve from the first end to the second end.

[0018] The intermediate coupling joint also comprises a cylindrical body that defines a bore therein. The bore is in fluid communication with the primary flow path. A co-axial sleeve is concentrically positioned around a wall of the tubular body, forming an annular region between the tubular body and the sleeve. The annular region defines a manifold region, with the manifold region placing the transport conduits of the load sleeve and the torque sleeve in fluid communication. Preferably, the co-axial sleeve is bolted into the tubular body, preserving spacing of the manifold region.

[0019] The load sleeve, the torque sleeve and the intermediate coupling joint form a coupling assembly that operatively connect the first and second base pipes along an open-hole portion of the wellbore. In one aspect, each of the load sleeve and the torque sleeve presents shoulders that receive the opposing ends of the coupling joint. O-rings may be used along the shoulders to preserve a fluid seal. At the same time, the coupling joint has opposing female threads for connecting the first and second base pipes.

[0020] In the present invention, the joint assembly further includes a flow port. The flow port resides adjacent the manifold and places the primary flow path in fluid communication with the secondary flow path. The manifold region also places respective transport conduits of the base pipes in fluid communication. Preferably, the flow port is in the tubular body of the coupling joint, although it may reside proximate an end of one or both of the threadedly connected base pipes.

[0021] In a preferred embodiment, the tubular bodies comprise blank pipes or, alternatively, perforated base pipes. The base pipes may be, for example, a series of joints threadedly connected to form the primary flow path. Alternatively, the tubular bodies may be

slotted pipes having a filter medium radially around the pipes and along a substantial portion of the pipes so as to form a sand screen.

[0022] The joint assembly is arranged to have Alternate Flow[®] technology. In this respect, each base pipe has at least two transport conduits. The transport conduits reside along an outer diameter of the base pipes, and are configured to transport fluids as a secondary flow path.

[0023] Various arrangements for the transport conduits may be used. Preferably, the at least two transport conduits represent six conduits radially disposed about the base pipe. The transport conduits may have different diameters and different lengths.

[0024] In one aspect, each of the transport conduits along the second base pipe extends substantially along the length of the second base pipe. In another aspect, each of the transport conduits along the first base pipe extends substantially along the length of the first base pipe, but one of the transport conduits has a nozzle intermediate the first and second ends of the first base pipe. In still another aspect, at least one of the transport conduits along the first base pipe has an outlet end intermediate the first and second ends of the first base pipe.

[0025] In one embodiment, the joint assembly further comprises an inflow control device. The inflow control device resides adjacent an opening in the flow port, or may even define the flow port. The inflow control device is configured to increase or decrease fluid flow through the flow port.

[0026] The joint assembly preferably also includes a packer assembly. The packer assembly comprises at least one sealing element. The sealing elements are configured to be actuated to engage a surrounding wellbore wall. The packer assembly also has an inner mandrel. Further the packer assembly has at least one transport conduit. The transport conduits extend along the inner mandrel and are in fluid communication with the transport conduits of the base pipes.

[0027] The sealing element for the packer assembly may include a mechanically-set packer. More preferably, the packer assembly has two mechanically-set packers or annular seals. These represent an upper packer and a lower packer. Each mechanically-set packer has a sealing element that may be, for example, from about 6 inches (15.2 cm) to 24 inches (61.0 cm) in length. Each mechanically-set packer also has an inner mandrel in fluid communication with the base pipe of the sand screens and the base pipe of the joint assembly.

[0028] Intermediate the at least two mechanically-set packers may optionally be at least one swellable packer element. The swellable packer element is preferably about 3 feet (0.91 meters) to 40 feet (12.2 meters) in length. In one aspect, the swellable packer element is

fabricated from an elastomeric material. The swellable packer element is actuated over time in the presence of a fluid such as water, gas, oil, or a chemical. Swelling may take place, for example, should one of the mechanically-set packer elements fails. Alternatively, swelling may take place over time as fluids in the formation surrounding the swellable packer element contact the swellable packer element.

[0029] A method for completing a wellbore in a subsurface formation is also provided herein. The wellbore preferably includes a lower portion completed as an open-hole.

[0030] In one aspect, the method includes providing a first base pipe and a second base pipe. The two base pipes are connected in series. Each base pipe comprises a tubular body. The tubular bodies each have a first end, a second end and a bore defined there between. The bores form a primary flow path for fluids. In a preferred embodiment, the tubular bodies comprise perforated base pipes.

[0031] Each of the base pipes also has at least two transport conduits. The transport conduits reside along an outer diameter of the base pipes for transporting fluids as a secondary flow path. Various arrangements for the transport conduits may be used. As discussed above, the transport conduits may have different diameters and different lengths.

[0032] The method also includes operatively connecting the second end of the first base pipe to the first end of the second base pipe. This is done by means of a coupling assembly. In one embodiment, the coupling assembly includes a load sleeve, a torque sleeve, and an intermediate coupling joint. The load sleeve, the torque sleeve, and the coupling joint form a coupling assembly as described above. Of note, the coupling joint includes a flow port residing adjacent the manifold region. The flow port places the primary flow path in fluid communication with the secondary flow path. The manifold region also places respective transport conduits of the base pipes in fluid communication.

[0033] The method further includes running the base pipes into the wellbore. The method then includes causing fluid to travel between the primary and secondary flow paths. In one aspect, the method further comprises producing hydrocarbon fluids through the base pipes of the first and second base pipes from at least one interval along the wellbore. Producing hydrocarbon fluids causes hydrocarbon fluids to travel from the secondary flow path to the primary flow path. In another aspect, the method further comprises injecting a fluid through the base pipes and into the wellbore along at least one interval. Injecting the fluid causes fluids to travel from the primary flow path to the secondary flow path.

[0034] In one embodiment, the joint assembly further comprises an inflow control device. The inflow control device resides adjacent an opening in the flow port. The inflow control

device is configured to increase or decrease fluid flow through the flow port. The inflow control device may be, for example, a sliding sleeve or a valve. The method may then further comprise adjusting the inflow control device to increase or decrease fluid flow through the flow port. This may be done through a radio frequency signal, a mechanical shifting tool, or hydraulic pressure.

[0035] Optionally, the method further includes providing a packer assembly. The packer assembly is also in accordance with the packer assembly described above in its various embodiments. The packer assembly includes at least one, and preferably two, mechanically-set packers. For example, each packer will have an inner mandrel, alternate flow channels around the inner mandrel, and a sealing element external to the inner mandrel.

BRIEF DESCRIPTION OF THE DRAWINGS

[0036] So that the manner in which the present inventions can be better understood, certain illustrations, charts and/or flow charts are appended hereto. It is to be noted, however, that the drawings illustrate only selected embodiments of the inventions and are therefore not to be considered limiting of scope, for the inventions may admit to other equally effective embodiments and applications.

[0037] Figure 1 is a cross-sectional view of an illustrative wellbore. The wellbore has been drilled through three different subsurface intervals, each interval being under formation pressure and containing fluids.

[0038] Figure 2 is an enlarged cross-sectional view of an open-hole completion of the wellbore of Figure 1. The open-hole completion at the depth of the three illustrative intervals is more clearly seen.

[0039] Figure 3A is a cross-sectional side view of a packer assembly, in one embodiment. Here, a base pipe is shown, with surrounding packer elements. Two mechanically-set packers are shown.

[0040] Figure 3B is a cross-sectional view of the packer assembly of Figure 3A, taken across lines 3B-3B of Figure 3A. Shunt tubes are seen within the swellable packer element.

[0041] Figure 4A is a cross-sectional side view of the packer assembly of Figure 3A. Here, perforated base pipes have been placed at opposing ends of the packer assembly. The base pipes utilize external shunt tubes.

[0042] Figure 4B provides a cross-sectional view of the screen assembly in Figure 4A, taken across lines 4B-4B of Figure 4A. Shunt tubes are seen outside of the base pipes to provide an alternative flowpath for a particulate slurry.

[0043] Figure 5A is a cross-sectional view of one of the mechanically-set packers of Figure 3A. Here, the mechanically-set packer is in its run-in position.

[0044] Figure 5B is a cross-sectional view of the mechanically-set packers of Figure 5A. Here, the mechanically-set packer has been activated and is in its set position.

[0045] Figure 6A is a side view of a wellbore completion apparatus as may be used in the joint assembly of the present invention, in one embodiment. The joint assembly includes a series of perforated base pipes connected using nozzle rings.

[0046] Figure 6B is a cross-sectional view of the wellbore completion apparatus of Figure 6A, taken across lines 6B-6B of Figure 6A. This shows one of the joint assemblies.

[0047] Figure 7A is an isometric view of a load sleeve as utilized as part of the joint assembly of Figure 6A, in one embodiment.

[0048] Figure 7B is an end view of the load sleeve of Figure 7A.

[0049] Figure 8 is a perspective view of a torque sleeve as utilized as part of the joint assembly of Figure 6A, in one embodiment.

[0050] Figure 9A is a side, cut-away view of a joint assembly of the present invention in one embodiment.

[0051] Figure 9B is a perspective view of a coupling joint as may be used in the joint assembly of Figure 6A.

[0052] Figure 9C is a cross-sectional view of the coupling joint of Figure 6A, taken across line 9C-9C of Figure 6A.

[0053] Figure 10 is an end view of a nozzle ring utilized along the joint assembly of Figure 6A.

[0054] Figures 11A and 11B are perspective views of a base pipe as may be utilized in the joint assembly of the present invention, in alternate embodiments.

[0055] Figures 12A and 12B present side views of joint assemblies of the present invention, in alternate embodiments.

[0056] Figures 13A and 13B present side views of joint assemblies of the present invention, in additional alternate embodiments.

[0057] Figure 14 is a flowchart for a method of completing a wellbore, in one embodiment. The method involves running a joint assembly into a wellbore, and causing fluids to flow between primary and secondary flow paths along the joint assembly.

DETAILED DESCRIPTION OF CERTAIN EMBODIMENTS

Definitions

[0058] As used herein, the term “hydrocarbon” refers to an organic compound that includes primarily, if not exclusively, the elements hydrogen and carbon. Hydrocarbons generally fall into two classes: aliphatic, or straight chain hydrocarbons, and cyclic, or closed ring hydrocarbons, including cyclic terpenes. Examples of hydrocarbon-containing materials include any form of natural gas, oil, coal, and bitumen that can be used as a fuel or upgraded into a fuel.

[0059] As used herein, the term “hydrocarbon fluids” refers to a hydrocarbon or mixtures of hydrocarbons that are gases or liquids. For example, hydrocarbon fluids may include a hydrocarbon or mixtures of hydrocarbons that are gases or liquids at formation conditions, at processing conditions or at ambient conditions (15° C and 1 atm pressure). Hydrocarbon fluids may include, for example, oil, natural gas, coal bed methane, shale oil, pyrolysis oil, pyrolysis gas, a pyrolysis product of coal, and other hydrocarbons that are in a gaseous or liquid state.

[0060] As used herein, the term “fluid” refers to gases, liquids, and combinations of gases and liquids, as well as to combinations of gases and solids, and combinations of liquids and solids.

[0061] As used herein, the term “subsurface” refers to geologic strata occurring below the earth's surface.

[0062] The term “subsurface interval” refers to a formation or a portion of a formation wherein formation fluids may reside. The fluids may be, for example, hydrocarbon liquids, hydrocarbon gases, aqueous fluids, or combinations thereof.

[0063] As used herein, the term “wellbore” refers to a hole in the subsurface made by drilling or insertion of a conduit into the subsurface. A wellbore may have a substantially circular cross section, or other cross-sectional shape. As used herein, the term “well,” when referring to an opening in the formation, may be used interchangeably with the term “wellbore.”

[0064] The terms “tubular member” or “tubular body” refer to any pipe or tubular device, such as a joint of casing or base pipe, a portion of a liner, or a pup joint.

[0065] The terms “sand control device” or “sand control segment” mean any elongated tubular body that permits an inflow of fluid into an inner bore or a base pipe while filtering out predetermined sizes of sand, fines and granular debris from a surrounding formation. A wire wrap screen around a slotted base pipe is an example of a sand control segment.

[0066] The term “transport conduits” means any collection of manifolds and/or alternate flow paths that provide fluid communication through or around a wellbore tool to allow a gravel slurry or other fluid to bypass the wellbore tool or any premature sand bridge in an annular region. Examples of such wellbore tools include (i) a packer having a sealing element, (ii) a sand screen or slotted pipe, and (iii) a blank pipe, with or without an outer protective shroud.

Description of Specific Embodiments

[0067] The inventions are described herein in connection with certain specific embodiments. However, to the extent that the following detailed description is specific to a particular embodiment or a particular use, such is intended to be illustrative only and is not to be construed as limiting the scope of the inventions.

[0068] Certain aspects of the inventions are also described in connection with various figures. In certain of the figures, the top of the drawing page is intended to be toward the surface, and the bottom of the drawing page toward the well bottom. While wells commonly are completed in substantially vertical orientation, it is understood that wells may also be inclined and or even horizontally completed. When the descriptive terms “up and down” or “upper” and “lower” or similar terms are used in reference to a drawing or in the claims, they are intended to indicate relative location on the drawing page or with respect to claim terms, and not necessarily orientation in the ground, as the present inventions have utility no matter how the wellbore is orientated.

[0069] **Figure 1** is a cross-sectional view of an illustrative wellbore **100**. The wellbore **100** defines a bore **105** that extends from a surface **101**, and into the earth’s subsurface **110**. The wellbore **100** is completed to have an open-hole portion **120** at a lower end of the wellbore **100**. The wellbore **100** has been formed for the purpose of producing hydrocarbons for processing or commercial sale. A string of production tubing **130** is provided in the bore **105** to transport production fluids from the open-hole portion **120** up to the surface **101**.

[0070] The wellbore **100** includes a well tree, shown schematically at **124**. The well tree **124** includes a shut-in valve **126**. The shut-in valve **126** controls the flow of production fluids from the wellbore **100**. In addition, a subsurface safety valve **132** is provided to block the flow of fluids from the production tubing **130** in the event of a rupture or catastrophic event above the subsurface safety valve **132**. The wellbore **100** may optionally have a pump (not shown) within or just above the open-hole portion **120** to artificially lift production fluids from the open-hole portion **120** up to the well tree **124**.

[0071] The wellbore **100** has been completed by setting a series of pipes into the subsurface **110**. These pipes include a first string of casing **102**, sometimes known as surface casing or a conductor. These pipes also include at least a second **104** and a third **106** string of casing. These casing strings **104**, **106** are intermediate casing strings that provide support for walls of the wellbore **100**. Intermediate casing strings **104**, **106** may be hung from the surface, or they may be hung from a next higher casing string using an expandable liner or liner hanger. It is understood that a pipe string that does not extend back to the surface (such as casing string **106**) is normally referred to as a “liner.”

[0072] In the illustrative wellbore arrangement of **Figure 1**, intermediate casing string **104** is hung from the surface **101**, while casing string **106** is hung from a lower end of casing string **104**. Additional intermediate casing strings (not shown) may be employed. The present inventions are not limited to the type of casing arrangement used.

[0073] Each string of casing **102**, **104**, **106** is set in place through a cement column **108**. The cement column **108** isolates the various formations of the subsurface **110** from the wellbore **100** and each other. The column of cement **108** extends from the surface **101** to a depth “L” at a lower end of the casing string **106**. It is understood that some intermediate casing strings may not be fully cemented.

[0074] An annular region **204** (seen in **Figure 2**) is formed between the production tubing **130** and the casing string **106**. A production packer **206** seals the annular region **204** near the lower end “L” of the casing string **106**.

[0075] In many wellbores, a final casing string known as production casing is cemented into place at a depth where subsurface production intervals reside. However, the illustrative wellbore **100** is completed as an open-hole wellbore. Accordingly, the wellbore **100** does not include a final casing string along the open-hole portion **120**.

[0076] In the illustrative wellbore **100**, the open-hole portion **120** traverses three different subsurface intervals. These are indicated as upper interval **112**, intermediate interval **114**, and lower interval **116**. Upper interval **112** and lower interval **116** may, for example, contain valuable oil deposits sought to be produced, while intermediate interval **114** may contain primarily water or other aqueous fluid within its pore volume. This may be due to the presence of native water zones, high permeability streaks or natural fractures in the aquifer, or fingering from injection wells. In this instance, there is a probability that water will invade the wellbore **100**.

[0077] Alternatively, upper **112** and intermediate **114** intervals may contain hydrocarbon fluids sought to be produced, processed and sold, while lower interval **116** may contain some

oil along with ever-increasing amounts of water. This may be due to coning, which is a rise of near-well hydrocarbon-water contact. In this instance, there is again the possibility that water will invade the wellbore **100**.

[0078] Alternatively still, upper **112** and lower **116** intervals may be producing hydrocarbon fluids from a sand or other permeable rock matrix, while intermediate interval **114** may represent a non-permeable shale or otherwise be substantially impermeable to fluids.

[0079] In any of these events, it is desirable for the operator to isolate selected intervals. In the first instance, the operator will want to isolate the intermediate interval **114** from the production string **130** and from the upper **112** and lower **116** intervals (by use of packer assemblies **210'** and **210''**) so that primarily hydrocarbon fluids may be produced through the wellbore **100** and to the surface **101**. In the second instance, the operator will eventually want to isolate the lower interval **116** from the production string **130** and the upper **112** and intermediate **114** intervals so that primarily hydrocarbon fluids may be produced through the wellbore **100** and to the surface **101**. In the third instance, the operator will want to isolate the upper interval **112** from the lower interval **116**, but need not isolate the intermediate interval **114**.

[0080] In the illustrative wellbore **100** of **Figure 1**, a series of base pipes **200** extends through the intervals **112**, **114**, **116**. The base pipes **200** and connected packer assemblies **210'**, **210''** are shown more fully in **Figure 2**.

[0081] Referring now to **Figure 2**, the base pipes **200** define an elongated tubular body **205**. Each base pipe **205** typically is made up of a plurality of pipe joints. The base pipe **200** (or each pipe joint making up the base pipe **200**) has perforations or slots **203** to permit the inflow of production fluids.

[0082] In another embodiment, the base pipes **200** are blank pipes having a filter medium (not shown) wound there around. In this instance, the base pipes **200** form sand screens. The filter medium may be a wire mesh screen or wire wrap fitted around the tubular bodies **205**. Alternatively, the filtering medium of the sand screen may comprise a membrane screen, an expandable screen, a sintered metal screen, a porous media made of shape-memory polymer (such as that described in U.S. Pat. No. 7,926,565), a porous media packed with fibrous material, or a pre-packed solid particle bed. The filter medium prevents the inflow of sand or other particles above a pre-determined size into the base pipe **200** and the production tubing **130**.

[0083] In addition to the base pipes **200**, the wellbore **100** includes one or more packer assemblies **210**. In the illustrative arrangement of **Figures 1** and **2**, the wellbore **100** has an upper packer assembly **210'** and a lower packer assembly **210''**. However, additional packer assemblies **210** or just one packer assembly **210** may be used. The packer assemblies **210'**, **210''** are uniquely configured to seal an annular region (seen at **202** of **Figure 2**) between the various sand control devices **200** and a surrounding wall **201** of the open-hole portion **120** of the wellbore **100**.

[0084] **Figure 2** provides an enlarged cross-sectional view of the open-hole portion **120** of the wellbore **100** of **Figure 1**. The open-hole portion **120** and the three intervals **112**, **114**, **116** are more clearly seen. The upper **210'** and lower **210''** packer assemblies are also more clearly visible proximate upper and lower boundaries of the intermediate interval **114**, respectively.

[0085] Concerning the packer assemblies themselves, each packer assembly **210'**, **210''** may have two separate packers. The packers are preferably set through a combination of mechanical manipulation and hydraulic forces. For purposes of this disclosure, the packers are referred to as being mechanically-set packers. The illustrative packer assemblies **210** represent an upper packer **212** and a lower packer **214**. Each packer **212**, **214** has an expandable portion or element fabricated from an elastomeric or a thermoplastic material capable of providing at least a temporary fluid seal against a surrounding wellbore wall **201**.

[0086] The elements for the upper **212** and lower **214** packers should be able to withstand the pressures and loads associated with a production process. The elements for the packers **212**, **214** should also withstand pressure load due to differential wellbore and/or reservoir pressures caused by natural faults, depletion, production, or injection. Production operations may involve selective production or production allocation to meet regulatory requirements. Injection operations may involve selective fluid injection for strategic reservoir pressure maintenance. Injection operations may also involve selective stimulation in acid fracturing, matrix acidizing, or formation damage removal.

[0087] The sealing surface or elements for the mechanically-set packers **212**, **214** need only be on the order of inches in order to affect a suitable hydraulic seal. In one aspect, the elements are each about 6 inches (15.2 cm) to about 24 inches (61.0 cm) in length.

[0088] It is preferred for the elements of the packers **212**, **214** to be able to expand to at least an 11-inch (about 28 cm) outer diameter surface, with no more than a 1.1 ovality ratio. The elements of the packers **212**, **214** should preferably be able to handle washouts in an 8-1/2 inch (about 21.6 cm) or 9-7/8 inch (about 25.1 cm) open-hole section **120**. The

expandable portions of the packers **212**, **214** will assist in maintaining at least a temporary seal against the wall **201** of the intermediate interval **114** (or other interval) as pressure increases during the gravel packing operation.

[0089] The upper **212** and lower **214** packers are set prior to production. The packers **212**, **214** may be set, for example, by sliding a release sleeve. This, in turn, allows hydrostatic pressure to act downwardly against a piston mandrel. The piston mandrel acts down upon a centralizer and/or packer elements, causing the same to expand against the wellbore wall **201**. The elements of the upper **212** and lower **214** packers are expanded into contact with the surrounding wall **201** so as to straddle the annular region **202** at a selected depth along the open-hole completion **120**. PCT Patent Appl. No. WO2012/082303 describes a packer that may be mechanically set within an open-hole wellbore.

[0090] Figure 2 shows a mandrel at **215** in the packers **212**, **214**. This may be representative of the piston mandrel, and other mandrels used in the packers **212**, **214** as described more fully in the PCT application.

[0091] As a “back-up” to the expandable packer elements within the upper **212** and lower **214** packers, the packer assemblies **210'**, **210''** also may include an intermediate packer element **216**. The intermediate packer element **216** defines a swelling elastomeric material fabricated from synthetic rubber compounds. Suitable examples of swellable materials may be found in Easy Well Solutions' Constrictor™ or SwellPacker™, and SwellFix's E-ZIP™. The swellable packer **216** may include a swellable polymer or swellable polymer material, which is known by those skilled in the art and which may be set by one of a conditioned drilling fluid, a completion fluid, a production fluid, an injection fluid, a stimulation fluid, or any combination thereof.

[0092] It is noted that a swellable packer **216** may be used in lieu of the upper **212** and lower **214** packers. The present inventions are not limited by the presence or design of any packer assembly unless expressly so stated in the claims.

[0093] The upper **212** and lower **214** packers may generally be mirror images of each other, except for the release sleeves that shear respective shear pins or other engagement mechanisms. Unilateral movement of a setting tool (not shown) will allow the packers **212**, **214** to be activated in sequence or simultaneously. The lower packer **214** is activated first, followed by the upper packer **212** as the shifting tool is pulled upward through an inner mandrel.

[0094] The packer assemblies **210'**, **210''** help control and manage fluids produced from different zones. In this respect, the packer assemblies **210'**, **210''** allow the operator to seal

off an interval from either production or injection, depending on well function. Installation of the packer assemblies **210'**, **210''** in the initial completion allows an operator to shut-off the production from one or more zones during the well lifetime to limit the production of water or, in some instances, an undesirable non-condensable fluid such as hydrogen sulfide.

[0095] **Figure 3A** presents an illustrative packer assembly **300** providing an alternate flowpath for a gravel slurry or other injection fluid. The packer assembly **300** is generally seen in cross-sectional side view. The packer assembly **300** includes various components that may be utilized to seal an annulus along the open-hole portion **120**.

[0096] The packer assembly **300** first includes a main body section **302**. The main body section **302** is preferably fabricated from steel or from steel alloys. The main body section **302** is configured to be a specific length **316**, such as about 40 feet (12.2 meters). The main body section **302** comprises individual pipe joints that will have a length that is between about 10 feet (3.0 meters) and 50 feet (15.2 meters). The pipe joints are typically threadedly connected end-to-end to form the main body section **302** according to length **316**.

[0097] The packer assembly **300** also includes opposing mechanically-set packers **304**. The mechanically-set packers **304** are shown schematically, and are generally in accordance with mechanically-set packer elements **212** and **214** of **Figure 2**. The packers **304** preferably include cup-type elastomeric elements that are less than 1 foot (0.3 meters) in length. As described further below, the packers **304** have alternate flow channels that uniquely allow the packers **304** to be set before a gravel slurry is circulated into the wellbore.

[0098] The packer assembly **300** also optionally includes a swellable packer. Alternatively, a short spacing **308** may be provided between the mechanically-set packers **304** in lieu of the swellable packer. When the packers **304** are mirror images of one another, the cup-type elements are able to resist fluid pressure from either above or below the packer assembly.

[0099] The packer assembly **300** also includes a plurality of shunt tubes **318**. The shunt tubes **318** may also be referred to as transport tubes or alternate flow channels or even jumper tubes. The transport tubes **318** are blank sections of pipe having a length that extends along the length **316** of the mechanically-set packers **304** and the swellable packer **308**. This enables the shunt tubes **318** to transport a fluid to different intervals **112**, **114** and **116** of the open-hole portion **120** of the wellbore **100**.

[00100] The packer assembly **300** also includes connection members. These may represent traditional threaded couplings. First, a neck section **306** is provided at a first end of the packer assembly **300**. The neck section **306** has external threads for connecting with a

threaded coupling box of a sand screen or other pipe. Then, a notched or externally threaded section **310** is provided at an opposing second end. The threaded section **310** serves as a coupling box for receiving an external threaded end of a base pipe. The base pipe may be a perforated pipe; alternatively, the base pipe may be a blank tubular body for a sand screen.

[00101] The neck section **306** and the threaded section **310** may be made of steel or steel alloys. The neck section **306** and the threaded section **310** are each configured to be a specific length **314**, such as 4 inches (10.2 cm) to 4 feet (1.2 meters) (or other suitable distance). The neck section **306** and the threaded section **310** also have specific inner and outer diameters. The neck section **306** has external threads **307**, while the threaded section **310** has internal threads **311**. These threads **307** and **311** may be utilized to form a seal between the packer assembly **300** and sand control devices or other pipe segments.

[00102] A cross-sectional view of the packer assembly **300** is shown in **Figure 3B**. **Figure 3B** is taken along the line **3B-3B** of **Figure 3A**. In **Figure 3B**, the swellable packer **308** is seen circumferentially disposed around the base pipe **302**. Various shunt tubes **318** are placed radially and equidistantly around the base pipe **302**. A central bore **305** is shown within the base pipe **302**. The central bore **305** receives production fluids during production operations and conveys them to the production tubing **130**.

[00103] **Figure 4A** presents a cross-sectional side view of a zonal isolation apparatus **400**, in one embodiment. The zonal isolation apparatus **400** includes the packer assembly **300** from **Figure 3A**. In addition, perforated base pipes **200** have been placed at opposing ends of the packer assembly **300**. The base pipes **200** utilize external shunt tubes. Transport tubes **318** from the packer assembly **300** are seen connected to transport conduits **218** on the base pipes **200**.

[00104] **Figure 4B** provides a cross-sectional side view of the zonal isolation apparatus **400**. **Figure 4B** is taken along the line **4B-4B** of **Figure 4A**. This is cut through one of the sand screens **200**. In **Figure 4B**, the slotted or perforated base pipe **205** is seen. This is in accordance with base pipe **205** of **Figures 1** and **2**. The central bore **105** is shown within the base pipe **205** for receiving production fluids during production operations.

[00105] The configuration of the transport conduits **218** is preferably concentric. This is seen in the cross-sectional views of **Figures 3B** and **4B**. However, the conduits **218** may be eccentrically designed. For example, Figure 2B in U.S. Pat. No. 7,661,476 presents a “Prior Art” arrangement for a sand control device wherein packing tubes **208a** and transport tubes **208b** are placed external to the base pipe **202** and surrounding filter medium **204**, forming an eccentric arrangement.

[00106] The packers **304** of **Figure 3A** are shown schematically. However, **Figures 5A** and **5B** provide more detailed views of a suitable mechanically-set packer **500** that may be used in the packer assembly of **Figure 3A**, in one embodiment.

[00107] The views of **Figures 5A** and **5B** provide cross-sectional views. In **Figure 5A**, the packer **500** is in its run-in position, while in **Figure 5B** the packer **500** is in its set position.

[00108] The packer **500** first includes an inner mandrel **510**. The inner mandrel **510** defines an elongated tubular body forming a central bore **505**. The central bore **505** provides a primary flow path of production fluids through the packer **500**. After installation and commencement of production, the central bore **505** transports production fluids to the bore **105** of the base pipes **200** (seen in **Figure 2**) and the production tubing **130** (seen in **Figures 1** and **2**).

[00109] The packer **500** also includes a first end **502**. Threads **504** are placed along the inner mandrel **510** at the first end **502**. The illustrative threads **504** are external threads. A box connector **514** having internal threads at both ends is connected or threaded on threads **504** at the first end **502**. The first end **502** of inner mandrel **510** with the box connector **514** is called the box end. The second end (not shown) of the inner mandrel **510** has external threads and is called the pin end. The pin end (not shown) of the inner mandrel **510** allows the packer **500** to be connected to the box end of a sand screen or other tubular body such as a stand-alone screen, a sensing module, a production tubing, or a blank pipe.

[00110] The box connector **514** at the box end **502** allows the packer **500** to be connected to the pin end of a sand screen or other tubular body such as a perforated base pipe **200**.

[00111] The inner mandrel **510** extends along the length of the packer **500**. The inner mandrel **510** may be composed of multiple connected segments, or joints. The inner mandrel **510** has a slightly smaller inner diameter near the first end **502**. This is due to a setting shoulder **506** machined into the inner mandrel. The setting shoulder **506** catches a release sleeve (not shown) in response to mechanical force applied by a setting tool.

[00112] The packer **500** also includes a piston mandrel **520**. The piston mandrel **520** extends generally from the first end **502** of the packer **500**. The piston mandrel **520** may be composed of multiple connected segments, or joints. The piston mandrel **520** defines an elongated tubular body that resides circumferentially around and substantially concentric to the inner mandrel **510**. An annulus **525** is formed between the inner mandrel **510** and the surrounding piston mandrel **520**. The annulus **525** beneficially provides a secondary flow path or alternate flow channels for fluids.

[00113] The packer **500** also includes a coupling **530**. The coupling **530** is connected and sealed (e.g., via elastomeric “o” rings) to the piston mandrel **520** at the first end **502**. The coupling **530** is then threaded and pinned to the box connector **514**, which is threadedly connected to the inner mandrel **510** to prevent relative rotational movement between the inner mandrel **510** and the coupling **530**. A first torque bolt is shown at **532** for pinning the coupling to the box connector **514**.

[00114] In one aspect, a NACA (National Advisory Committee for Aeronautics) key **534** is also employed. The NACA key **534** is placed internal to the coupling **530**, and external to a threaded box connector **514**. A first torque bolt is provided at **532**, connecting the coupling **530** to the NACA key **534** and then to the box connector **514**. A second torque bolt is provided at **536** connecting the coupling **530** to the NACA key **534**. NACA-shaped keys can (a) fasten the coupling **530** to the inner mandrel **510** via box connector **514**, (b) prevent the coupling **530** from rotating around the inner mandrel **510**, and (c) streamline the flow of slurry along the annulus **512** to reduce friction.

[00115] Within the packer **500**, the annulus **525** around the inner mandrel **510** is isolated from the main bore **505**. In addition, the annulus **525** is isolated from a surrounding wellbore annulus (not shown). The annulus **525** enables the transfer of gravel slurry or other fluid from alternative flow channels (such as transport conduits **218**) through the packer **500**. Thus, the annulus **525** becomes the alternative flow channel(s) for the packer **500**.

[00116] In operation, an annular space **512** resides at the first end **502** of the packer **500**. The annular space **512** is disposed between the box connector **514** and the coupling **530**. The annular space **512** receives slurry from alternate flow channels of a connected tubular body, and delivers the slurry to the annulus **525**. The tubular body may be, for example, an adjacent sand screen, a blank pipe, or a zonal isolation device.

[00117] The packer **500** also includes a load shoulder **526**. The load shoulder **526** is placed near the end of the piston mandrel **520** where the coupling **530** is connected and sealed. A solid section at the end of the piston mandrel **520** has an inner diameter and an outer diameter. The load shoulder **526** is placed along the outer diameter. The inner diameter has threads and is threadedly connected to the inner mandrel **510**. At least one alternate flow channel is formed between the inner and outer diameters to connect flow between the annular space **512** and the annulus **525**.

[00118] The load shoulder **526** provides a load-bearing point. During rig operations, a load collar or harness (not shown) is placed around the load shoulder **526** to allow the packer **500** to be picked up and supported with conventional elevators. The load shoulder **526** is

then temporarily used to support the weight of the packer **500** (and any connected completion devices such as sand screen joints already run into the well) when placed in the rotary floor of a rig. The load may then be transferred from the load shoulder **526** to a pipe thread connector such as box connector **514**, then to the inner mandrel **510** or base pipe **205**, which is pipe threaded to the box connector **514**.

[00119] The packer **500** also includes a piston housing **540**. The piston housing **540** resides around and is substantially concentric to the piston mandrel **520**. The packer **500** is configured to cause the piston housing **540** to move axially along and relative to the piston mandrel **520**. Specifically, the piston housing **540** is driven by the downhole hydrostatic pressure. The piston housing **540** may be composed of multiple connected segments, or joints.

[00120] The piston housing **540** is held in place along the piston mandrel **520** during run-in. The piston housing **540** is secured using a release sleeve and release key. Operation of the release sleeve and the release key is set forth in detail in U.S. Patent Publication No. 2012/0217010 and is incorporated herein by reference in its entirety.

[00121] The release key is shown at **715**. As shown in Figures 7A and 7B of the co-pending application, an outer edge of the release key **715** has a rugged surface, or teeth. The teeth for the release key are shown at **736**. The teeth of the release key are angled and configured to mate with a reciprocal rugged surface within the piston housing **540**. The mating rugged surface (or teeth) for the piston housing **540** are shown at **546**. The teeth reside on an inner face of the piston housing **540**. When engaged, the teeth **736**, **546** prevent movement of the piston housing **540** relative to the piston mandrel **520** or the inner mandrel **510**.

[00122] The packer **500** also preferably includes a centralizing member **550**. The centralizing member **550** is actuated by the movement of the piston housing **540**. The centralizing member **550** may be, for example, as described in U.S. Patent Publication No. 2011/0042106.

[00123] The packer **500** further includes a sealing element **555**. As the centralizing member **550** is actuated and centralizes the packer **500** within the surrounding wellbore, the piston housing **540** continues to actuate the sealing element **555** as described in U.S. Patent Publication No. 2009/0308592.

[00124] In **Figure 5A**, the centralizing member **550** and sealing element **555** are in their run-in position. In **Figure 5B**, the centralizing member **550** and connected sealing element **555** have been actuated. This means the piston housing **540** has moved along the piston

mandrel **520**, causing both the centralizing member **550** and the sealing element **555** to engage the surrounding wellbore wall.

[00125] As noted, movement of the piston housing **540** takes place in response to hydrostatic pressure from wellbore fluids, including the gravel slurry. In the run-in position of the packer **500** (shown in **Figure 5A**), the piston housing **540** is held in place by the release sleeve **710** and associated piston key **715**. Operation of the release sleeve and the release key is again set forth in detail in U.S. Patent Publication No. 2012/0217010, particularly in connection with Figures 7A and 7B therein.

[00126] To move the release the release sleeve, a setting tool is used. An illustrative setting tool is shown at **750** in **Figure 7C** of the co-pending provisional patent application. Preferably, the setting tool is run into the wellbore with a washpipe string (not shown). Movement of the washpipe string along the wellbore can be controlled at the surface. Movement of the washpipe string causes a pin to be sheared, producing movement of the release sleeve, and thereby allowing the release key to disengage from the piston housing **540**.

[00127] After the shear pins have been sheared, the piston housing **540** is free to slide along an outer surface of the piston mandrel **520**. Hydrostatic pressure then acts upon the piston housing **540** to translate it downward relative to the piston mandrel **520**. More specifically, hydrostatic pressure from the annulus **525** acts upon a shoulder **542** in the piston housing **540**. This is seen best in **Figure 5B**. The shoulder **542** serves as a pressure-bearing surface. A fluid port **528** is provided through the piston mandrel **520** to allow fluid to access the shoulder **542**. The pressure is applied to the piston housing **540** to ensure that the packer elements **655** engage against the surrounding wellbore.

[00128] To further understand features of the illustrative mechanically-set packer **500**, reference is again made to U.S. Patent Publication No. 2012/0217010. This co-pending application presents additional cross-sectional views, shown at Figures 6C, 6D, 6E, and 6F of this application. Descriptions of the cross-sectional views need not be repeated herein.

[00129] It is necessary to connect the packer **500** to the base pipes **200**. It is further necessary to sections of base pipe joints together to form a base pipe **200**. These operations may be done using a unique coupling assembly that employs a load sleeve, a torque sleeve, and an intermediate coupling joint.

[00130] **Figure 6A** offers a side view of a joint assembly **600** as may be used in the wellbore completion apparatus of the present invention, in one embodiment. The joint assembly **600** includes a plurality of base pipes **610a**, **610b**, . . . **610f**. The base pipes **610a**,

610b, . . . **610f** are connected in series using nozzle rings **910a**, **910b**, . . . **910n**. Preferably, the base pipes are slotted or perforated pipes.

[00131] **Figure 6B** is a cross-sectional view of the joint assembly **600** of **Figure 6A**, taken across line **6B-6B** of **Figure 6A**. Specifically, the view is taken through a base pipe **610a**.

[00132] Referring back to **Figure 6A**, the joint assembly **600** has a first or upstream end **602** and a second or downstream end **604**. A load sleeve **700** is operably attached at or near the first end **602**, while a torque sleeve **800** is operably attached at or near the second end **604**. The sleeves **700**, **800** are preferably manufactured from a material having sufficient strength to withstand the contact forces achieved during running operations. One preferred material is a high yield alloy material such as S165M.

[00133] **Figure 7A** is an isometric view of a load sleeve **700** as utilized as part of the joint assembly of **Figure 6A**, in one embodiment. **Figure 7B** is an end view of the load sleeve **700** of **Figure 7A**. As can be seen, the load sleeve **700** comprises an elongated body **720** of substantially cylindrical shape. The load sleeve **700** has an outer diameter and a bore extending from a first end **702** to a second end **704**.

[00134] The load sleeve **700** includes at least two transport conduits **708a**, **708b**, . . . **708f**. In the view of **Figure 6B**, six separate transport conduits are shown. The transport conduits are disposed exterior to the inner diameter and interior to the outer diameter.

[00135] In some embodiments of the present techniques, the load sleeve **700** includes beveled edges **716** at the downstream end **704** for easier welding of the transport conduits **708a**, **708b**, . . . **708i** thereto. The preferred embodiment also incorporates a plurality of radial slots or grooves **718** in the face of the downstream or second end **704**.

[00136] Preferably, the load sleeve **700** includes radial holes **714** between its downstream end **704** and a load shoulder **712**. The radial holes **714** are dimensioned to receive threaded connectors, or bolts, (not shown). The connectors provide a fixed orientation between the load sleeve **700** and the base pipe **610**. For example, there may be nine holes **714** in three groups of three spaced substantially equally around the outer circumference of the load sleeve **700** to provide the most even distribution of weight transfer from the load sleeve **700** to the base pipe **610**.

[00137] Referring next to **Figure 8**, **Figure 8** is a perspective view of a torque sleeve **800** utilized as part of the joint assembly **600** of **Figure 6A**, in one embodiment. The torque sleeve **800** is positioned at the downstream or second end **604** of the illustrative assembly **600**.

[00138] The torque sleeve **800** includes an upstream or first end **802** and a downstream or second end **804**. The torque sleeve **800** also has an inner diameter **806**. The torque sleeve **800** further has various alternate path channels, or transport conduits **808a-808i**. The transport conduits **808a-808f** extend from the first end **802** to the second end **804**. In the event that the torque sleeve **800** is in fluid communication with a sand screen, the channels may also represent packing conduits **808g-808i**. The packing conduits **808g-808i** will terminate before reaching the second end **804** and release slurry through nozzles **818**.

[00139] Preferably, the torque sleeve **800** includes radial holes **814** between the upstream end **802** and a lip portion **810** to accept threaded connectors, or bolts, therein. The connectors provide a fixed orientation between the torque sleeve **800** and the base pipe **610**. For example, there may be nine holes **814** in three groups of three, spaced equally around the outer circumference of the torque sleeve **800**. In the embodiment of **Figure 8**, the torque sleeve **800** has beveled edges **816** at the upstream end **802** for easier attachment of the transport conduits **808** thereto.

[00140] The load sleeve **700** and the torque sleeve **800** enable immediate connections with packer assemblies or other elongated downhole tools while aligning transport conduits. It is desirable to mechanically connect the load sleeve **700** to the torque sleeve **800**. This is done through an intermediate threaded coupling joint **900**.

[00141] **Figure 9A** presents a side view of a joint assembly **901** of the present invention in one embodiment. In **Figure 9A**, the joint **901** includes a load sleeve **700** and a torque sleeve **800**. The load sleeve **700** and the torque sleeve **800** are connected by means of a coupling joint **900**.

[00142] **Figure 9B** is a perspective view of the coupling joint **900** as may be used in the joint assembly **901** of **Figure 9A**. The coupling joint **900** is a generally cylindrical body having an outer wall **910**. The coupling joint **900** has a first end **902** and a second end **904**. The first end **902** contains female threads (not shown) that threadedly connect to male threads of the torque sleeve **800**. Similarly, the second end **904** contains female threads **907** that threadedly connect to male threads of the load sleeve **700**.

[00143] In a more preferred arrangement, the outer wall **910** defines a co-axial sleeve. Opposing ends of the co-axial sleeve have respective shoulders that land on the load sleeve **700** and the torque sleeve **800**.

[00144] Interior to the coupling joint **900** is a main body **905**. The main body **905** defines a bore having opposing ends. The opposing ends threadedly connect to respective base pipes **610**. An annular region is formed between an outer diameter of the main body **905** and an

inner diameter of the outer wall **910** (the co-axial sleeve). This is referred to as a manifold **915**.

[00145] **Figure 9C** is a cross-sectional view of the coupling joint **900** of **Figure 6A** and **Figure 9B**, taken across line **9C-9C** of **Figure 6A**. In **Figure 9C**, the manifold **915** is more clearly seen. In the arrangement of **Figure 9C**, the manifold **915** is not open, but is made up of separate transport conduits **908**. Six transport conduits **908** are provided. The transport conduits **908** enable transport tubes **708a**, **708b**, . . . **708f** in the load sleeve **700** and transport tubes **808a**, **808b**, . . . **808f** in the torque sleeve **800** to be placed in fluid communication. The transport conduits **908** are part of a secondary flow path.

[00146] In **Figure 9C**, optional packing conduits **918** are also provided. The packing conduits **918** are isolated from the transport conduits **908**. The packing conduits **918** place any packing conduits in the load sleeve **700** with any packing conduits **808g-808i** in the torque sleeve **800**. The packing conduits **918** are only needed if the tool assembly **901** is used for gravel packing.

[00147] The coupling joint **900** offers a plurality of torque spacers **909a**, **909b**, . . . **909e**. The torque spacers **909a**, **909b**, . . . **909e** support the annular region **915** between the main body **905** and the surrounding co-axial sleeve **910**. Stated another way, the torque spacers **909a**, **909b**, . . . **909e** provide structural integrity to the co-axial sleeve **910** to provide a substantially concentric alignment with the main body **905**. Additionally, the torque spacers **909a**, **909b**, . . . **909e** may be configured to prevent tortuous fluid flow.

[00148] In the present invention, the coupling joint **900** further includes one or more flow ports **920**. These are seen in both **Figures 9B** and **9C**. The flow ports **920** provide fluid communication between the inner bore defined by the main body **905** and at least two of the transport conduits **908**. In the view of **Figure 9C**, three separate flow ports **920** are provided.

[00149] Returning to **Figure 9A**, **Figure 9A** shows a primary flow path at **618** and a secondary flow path at **620**. The primary flow path **618** represents a flow path through the bore of the base pipes **610a**, **610b**, . . . **610f**, the bore of the load sleeve **700**, the bore of the main body **905**, and the bore of the torque sleeve **800**. The secondary flow path **620**, in turn, represents a flow path through the transport conduits **708a**, **708b**, . . . **708f** of the load sleeve **700**, the manifold **915** of the coupling joint and the transport conduits **808a**, **808b**, . . . **808f** in the torque sleeve **800**. Additionally, the secondary flow path includes transport conduits **930** external to the base pipes **610**.

[00150] Returning to **Figure 6A**, it can be seen that the illustrative joint assembly **600** includes a plurality of base pipes **610a**, **610b**, . . . **610f**. The base pipes **610a**, **610b**, . . . **610f**

represent separate joints. In order to connect the joints together while maintaining alignment with the transport conduits **930**, nozzle rings **1000** are used.

[00151] **Figure 10** is an end view of a nozzle ring **1000** utilized as part of the joint assembly **600** of **Figure 6A**. The nozzle ring **1000** is adapted and configured to fit around the base pipe **610a**, **610b**, . . . **610e**, the transport conduits **930** and, if used, packing conduits. The nozzle ring **1000** is shown in the side view of **Figure 9A** as nozzle rings **1010a**, **1010b**, . . . **1010n**. Each nozzle ring **1000** is held in place by wire-wrap welds at the grooves similar to item **812** in **Figure 8**. Split rings (not shown) may be installed at the interface between each nozzle ring **1000** and the wire-wrap.

[00152] The nozzle ring **1000** includes a plurality of channels **1004a**, **1004b**, . . . **1004i** to accept the transport tubes **930** and, optionally, packing tubes **608g**, **608h**, **608i**. Each channel **1004a**, **1004b**, . . . **1004i** extends through the nozzle ring **1000** from an upstream or first end to a downstream or second end.

[00153] Additional details concerning the load sleeve **700**, the torque sleeve **800**, the coupling joint **900** and the nozzle ring **1000** are provided in U.S. Pat. No. 7,938,184. Figures 3A, 3B, 3C, 4A, 4B, 5A, 5B, 6 and 7 present details concerning components of a joint assembly in the context of using a sand screen. These figures and accompanying text are incorporated herein by reference.

[00154] Each base pipe **610a**, **610b**, . . . **610f** has at least two transport conduits (visible at **930** in **Figure 9A**). The transport conduits **930** deliver fluid into an annular region defined by an outer diameter of the base pipes **610a**, **610b**, . . . **610e** and the surrounding open-hole formation in a wellbore.

[00155] **Figures 11A** and **11B** offer perspective cut-away views of a base pipe **610** as may be utilized in the joint assembly of the present invention, in alternate embodiments. The base pipe **610** provides an expanded view of the base pipes **610** shown in **Figure 6**. The base pipe **610** is designed to be run into a wellbore and along an open-hole formation (not shown).

[00156] In each of **Figures 11A** and **11B**, the base pipe **610** includes a tubular body **615**. The tubular body **615** defines a bore **935** within an inner diameter. The bore **935** is part of the primary flow path offered for fluid flow herein. In one aspect, the base pipe **615** is between about 8 feet and 40 feet (2.4 meters to 12.2 meters) in length.

[00157] In the arrangement of **Figures 11A** and **11B**, the base pipe **610** is a perforated pipe. A plurality of slots **626** is shown along the length of the base pipe **610**. Slots **626** are comparable to slots **203** of **Figure 2**.

[00158] Along an outer diameter of the tubular body **615** is a plurality of conduits **932**, **934**. The conduits **932**, **934** are transport conduits, and are part of the secondary flow path offered for fluid flow herein. The conduits **932**, **934** are preferably constructed from steel, such as a lower yield, weldable steel.

[00159] The transport conduits **932**, **934** are designed to carry a fluid. If the wellbore is formed for a producer, the fluid will be hydrocarbon fluids. Alternatively, the fluid may be a treatment fluid for conditioning the formation, such as an acid solution. If the wellbore is formed for injection, the fluid will be an aqueous fluid.

[00160] In **Figure 11A**, four transport conduits **932**, **934** are shown. However, it is understood that more than or fewer than four conduits **932**, **934** may be employed, so long as there are at least two. In the arrangement of **Figure 11A**, each of the transport conduits **932**, **934** extends along the entire length of the tubular body **615**. However, transport conduit **934** includes nozzle **936** along the tubular body **615** for delivering fluids into the annulus. Preferably, nozzles **936** are spaced at about six foot intervals.

[00161] In **Figure 11B**, four transport conduits **932**, **934** are again shown. However, in the arrangement of **Figure 11B** at least one of the transport conduits **934** terminates along the length of the tubular body **615**. In this instance, no nozzles are required for delivering fluids into the annulus.

[00162] As noted, the base pipe **610** is designed to be run into an open-hole portion of a wellbore. The base pipe **610** is ideally run in pre-connected joints using nozzle rings, such as the nozzle ring **1000** of **Figure 10**. Sections of pre-connected joints are then connected at the rig using a coupling assembly, such as the assembly **901** of **Figure 9A**. The coupling assembly will preferably include a load sleeve, such as the load sleeve **700** of **Figures 7A** and **7B**, a torque sleeve, such as the torque sleeve **800** of **Figure 8**, and an intermediate coupling joint, such as the coupling joint **900** of **Figures 9A** and **9B**.

[00163] **Figures 12A** and **12B** present side, cut-away views of a joint assembly **1200** of the present invention, in alternate embodiments. In each of **Figures 12A** and **12B**, a base pipe **610** is seen. The base pipe **610** includes transport conduits **932**, **934** in accordance with base pipe **610** of **Figures 11A** and **11B** described above. The base pipe **610** may actually be several joints of base pipe threadedly connected in series using nozzle rings.

[00164] At opposing ends of the base pipe **610** are coupling assemblies **1250**. Each of the coupling assemblies **1250** is configured to have a coupling joint **900**. The coupling joint **900** includes a main body **905** and a surrounding co-axial sleeve **910** in accordance with **Figure**

9B. Additionally, the coupling joint **900** includes a manifold region **915** and at least one flow port **920** in accordance with **Figure 9C**.

[00165] Additional features of the coupling joint **900** include a torque spacer **909** and optional bolts **914**. The torque spacer **909** and bolts **914** hold the main body **905** in fixed concentric relation relative to the co-axial sleeve **910**. Also, an inflow control device **924** is shown. The inflow control device **924** allows the operator to selectively open, partially open, close or partially close a valve associated with the flow port **920**. This may be done, for example, by sending a tool downhole on a wireline or an electric line or on coiled tubing that has generates a wireless signal. The signal may be, for example, a Bluetooth signal or an Infrared (IR) signal. The inflow control device **924** may be, for example, a sliding sleeve or a valve. In one aspect, the flow port is an inflow control device.

[00166] The coupling assemblies **1250** also each have a torque sleeve **800** and a load sleeve **700**. The torque sleeve **800** and the load sleeve **700** enable connections with the base pipe **610** while aligning shunt tubes. U.S. Patent No. 7,661,476 discloses a production string (referred to as a joint assembly) that employs a series of sand screen joints. The sand screen joints are placed between a “load sleeve” and a “torque sleeve.” The ‘476 patent is incorporated by reference herein in its entirety.

[00167] In **Figure 12A**, the transport conduit **934** has a shortened length. At the end of the shortened transport conduit is a valve **942**. The valve **942** allows an operator to selectively open and close the end of the transport conduit **934** to fluid flow. This again may be done by sending a tool downhole on a wireline or an electric line or on coiled tubing that has generates a wireless signal.

[00168] In **Figure 12B**, the transport conduit **934** has a full length, but includes nozzles **936**. Associate with the respective nozzles are valves **942**. The valves **942** allow for selective opening and closing of the transport conduit **934** to fluid flow.

[00169] **Figures 13A** and **13B** present side views of a joint assembly **1300A**, **1300B** of the present invention, in alternate embodiments. In each of **Figures 13A** and **13B**, base pipes **610** are shown in series. The base pipes **610** may be individual base pipes, or may be joints of base pipe connected in series through nozzle rings, such as the ring **1000** of **Figure 10**. In either event, the base pipes **610** are connected in a wellbore using coupling assemblies **1250**.

[00170] The coupling assemblies **1250** may be in accordance with the views shown in **Figures 9A**, **12A** and **12B**. In this respect, the couplings assemblies will include a torque sleeve **800**, a load sleeve **700**, and an intermediate coupling joint **900**. Of interest, the coupling joint **900** will include one or more flow ports **920** that place a primary flow path

provided through the base pipes **610** in fluid communication with a secondary flow path provided through the transport conduits **932**, **934**.

[00171] In the joint assembly **1300A** of **Figure 13A**, separate assembly portions “A” and “B” are shown. In portion “A”, only transport conduits **932** are provided. Thus, there is no fluid communication between the primary flow path and the wellbore annulus in which the transport conduits **932** reside. In portion “B”, transport conduits **932** and **934** are shown. Transport conduit **934** provides fluid communication between the primary flow path and the wellbore annulus. Thus, a fixed degree of flow control is provided.

[00172] In the joint assembly **1300B** of **Figure 13B**, separate assembly portions “A” and “B” are again shown. Indeed, two separate pairs of portions “A” and “B” are provided. Of interest, a packer assembly **1360** is seen along the joint assembly **1300B**. In the illustrative assembly of **Figure 13A**, the packer assembly employs a swellable packer element **1365**. However, a mechanically-set packer, such as packer **500** shown in **Figure 5**, may alternatively be used. The packer assembly **1360** is used to isolate zones above and below the sealing element **1365**.

[00173] Also of interest, an optional plug **1325** is seen in the joint assembly **1300B**. The plug **1325** is placed in the bore of the base pipe **610**. This isolates the portions “A” and “B” from any formations below the assembly **1300B**. For example, the plug may isolate section **116** of the open hole portion **120** of **Figure 2**.

[00174] Based on the above descriptions, a method for completing an open-hole wellbore is provided herein. The method is presented in **Figure 14**. **Figure 14** provides a flow chart presenting steps for a method **1400** of completing a wellbore in a subsurface formation, in certain embodiments. The wellbore includes a lower portion completed as an open-hole.

[00175] The method **1400** first includes providing a first base pipe and a second base pipe. This is shown at Box **1410**. The two base pipes are connected in series. Each base pipe comprises a tubular body. The tubular bodies each have a first end, a second end and a bore defined there between. The bore forms a primary flow path for fluids.

[00176] In a preferred embodiment, the tubular bodies comprise perforated base pipes. The base pipes may be, for example, a series of joints threadedly connected to form the primary flow path. Alternatively, the tubular bodies may be blank pipes having a filter medium radially around the pipes and along a substantial portion of the pipes so as to form a sand screen.

[00177] Each of the base pipes also has at least two transport conduits. The transport conduits reside along an outer diameter of the base pipes for transporting fluids as a secondary flow path.

[00178] The method also includes operatively connecting the second end of the first base pipe to the first end of the second base pipe. This step is shown in Box **1420**. The connecting step is done by means of a coupling assembly. In one aspect, the coupling assembly includes a load sleeve, a torque sleeve, and an intermediate coupling joint, with the load sleeve, the torque sleeve and the coupling joint being arranged and connected as described above such as in **Figures 12A and 12B**.

[00179] Of note, a flow port resides adjacent the manifold in the coupling joint. The flow port places the primary flow path in fluid communication with the secondary flow path. The manifold region also places respective transport conduits of the base pipes in fluid communication.

[00180] Various arrangements for the transport conduits may be used. Preferably, the at least two transport conduits represent six conduits radially disposed about the base pipe. The transport conduits may have different diameters and different lengths.

[00181] In one aspect, each of the transport conduits along the second base pipe extends substantially along the length of the second base pipe. In another aspect, each of the transport conduits along the first base pipe extends substantially along the length of the first base pipe, but one of the transport conduits has a nozzle intermediate the first and second ends of the first base pipe. The method then further comprises adjusting the valve to increase or decrease fluid flow through the valve. In still another aspect, at least one of the transport conduits along the first base pipe has an outlet end intermediate the first and second ends of the first base pipe.

[00182] In one embodiment, the joint assembly further comprises an inflow control device. The inflow control device resides adjacent an opening in the flow port. The inflow control device is configured to increase or decrease fluid flow through the flow port. The inflow control device may be, for example, a sliding sleeve or a valve. The method may then further comprise adjusting the inflow control device to increase or decrease fluid flow through the flow port. This may be done through a radio frequency signal, a mechanical shifting tool, or hydraulic pressure.

[00183] The method **1400** also includes running the base pipes into the wellbore. This is seen at Box **1430**.

[00184] Optionally, the method **1400** further includes running a packer assembly into the wellbore with the first and second base pipes. This is shown at Box **1440**. The packer assembly has at least one sealing element. The packer assembly may be in accordance with the packer assembly **300** described above in connection with **Figure 3A**. The packer assembly may include at least one, and preferably two, mechanically-set packers. These represent an upper packer and a lower packer. Each packer will have an inner mandrel, alternate flow channels around the inner mandrel, and a sealing element external to the inner mandrel. Each mechanically-set packer has a sealing element that may be, for example, from about 6 inches (15.2 cm) to 24 inches (61.0 cm) in length. The packers may further have a movable piston housing and an elastomeric sealing element. The sealing element is operatively connected to a piston housing. This means that sliding the movable piston housing along each packer (relative to the inner mandrel) will actuate the respective sealing elements into engagement with the surrounding wellbore.

[00185] The method **1400** may further include running a setting tool into the inner mandrel of the packers, and releasing the movable piston housing in each packer from its fixed position. A working line with the setting tool is pulled along the inner mandrel of each packer. This serves to shear the at least one shear pin and shift the release sleeves in the respective packers. Shearing the shear pin allows the piston housing to slide along the piston mandrel and exert a force that sets the elastomeric packer elements.

[00186] A swellable packer element may also be employed intermediate a pair of mechanically-set packers. The swellable packer element is preferably about 3 feet (0.91 meters) to 40 feet (12.2 meters) in length. In one aspect, the swellable packer element is fabricated from an elastomeric material. The swellable packer element is actuated over time in the presence of a fluid such as water, gas, oil, or a chemical. Swelling may take place, for example, should one of the mechanically-set packer elements fails. Alternatively, swelling may take place over time as fluids in the formation surrounding the swellable packer element contact the swellable packer element.

[00187] In any instance, the method **1400** will then also include setting the at least one sealing element. This is provided at Box **1440**.

[00188] The method **1400** additionally includes causing fluid to travel between the primary flow path and the secondary flow path. This is indicated at Box **1460**. Causing fluid to travel may mean producing hydrocarbon fluids. In this instance, fluids travel from at least one of the transport conduits in the annulus into the base pipes. Alternatively, causing fluid to travel may mean injecting an aqueous solution into the formation surrounding the base

pipes. In this instance, fluids travel from the base pipes and into at least one of the transport conduits. Alternatively still, causing fluid to travel may mean injecting a treatment fluid into the formation. In this instance, fluids such as acid travel from the base pipes and into at least one of the transport conduits, and then into the formation. The treatment fluid may be, for example, a gas, an aqueous solution, steam, diluent, solvent, fluid loss control material, viscosified gel, viscoelastic fluid, chelating agent, acid, or a chemical consolidation agent.. In all instances, fluids travel through the at least one flow port along the coupling joint.

[00189] The above method **1400** may be used to selectively produce from or inject into multiple zones. This provides enhanced subsurface production or injection control in a multi-zone completion wellbore. Further, the method **1400** may be used to inject a treating fluid along an open-hole formation in a multi-zone completion wellbore.

[00190] While it will be apparent that the inventions herein described are well calculated to achieve the benefits and advantages set forth above, it will be appreciated that the inventions are susceptible to modification, variation and change without departing from the spirit thereof. Improved methods for completing an open-hole wellbore are provided so as to seal off one or more selected subsurface intervals. An improved zonal isolation apparatus is also provided. The inventions permit an operator to produce fluids from or to inject fluids into a selected subsurface interval.

CLAIMS

What is claimed is:

1. A method for completing a wellbore in a subsurface formation, the method comprising:
 - providing a first base pipe and a second base pipe, with each base pipe comprising:
 - a tubular body having a first end, a second end and a bore there between forming a primary flow path; and
 - at least two transport conduits along an outer diameter for transporting fluids as a secondary flow path;
 - operatively connecting the second end of the first base pipe to the first end of the second base pipe by means of a coupling assembly, the coupling assembly comprising a manifold that receives respective transport conduits of the base pipes, and a flow port adjacent the manifold that places the primary flow path in fluid communication with the secondary flow path;
 - running the base pipes into the wellbore; and
 - causing fluid to travel between the primary and secondary flow paths.
2. The method of claim 1, wherein the tubular bodies comprise perforated base pipes.
3. The method of claim 2, wherein each of the base pipes comprises a series of perforated joints threadedly connected to form the primary flow path.
4. The method of claim 1, wherein the coupling assembly further comprises:
 - a load sleeve mechanically connected proximate to the first end of the second base pipe;
 - a torque sleeve mechanically connected proximate to the second end of the first base pipe; and
 - an intermediate coupling joint comprising a main tubular body defining a bore in fluid communication with the primary flow path, the main tubular body having a first end and a second end, wherein the first end is threadedly connected to the second end of the first base pipe, and the second end is threadedly connected to the first end of the second base pipe.

5. The method of claim 4, wherein:
the load sleeve and the torque sleeve each comprises:
a tubular body defining an inner bore therein in fluid communication with the primary flow path, and
transport conduits disposed longitudinally along the tubular body in fluid communication with the secondary flow path; and
the coupling joint further comprises:
a coaxial sleeve positioned around the tubular body, the sleeve forming an annular region between the tubular body and the sleeve, with the annular region defining the manifold, and the manifold placing the transport conduits of the load sleeve and of the torque sleeve in fluid communication.
6. The method of claim 5, wherein the flow port comprises (i) a through opening in the tubular body of the coupling joint, (ii) a through-opening in the second end of the first tubular body, (iii) a through-opening in the first end of the second tubular body, or (iv) combinations thereof.
7. The method of claim 1, wherein the tubular bodies comprise slotted pipes having a filter medium radially around the pipes and along a substantial portion of the pipes so as to form a sand screen.
8. The method of claim 7, wherein the filtering medium of each sand screen comprises a wire-wrapped screen, a slotted liner, a ceramic screen, a membrane screen, an expandable screen, a sintered metal screen, a wire-mesh screen, a shape memory polymer, or a pre-packed solid particle bed.
9. The method of claim 1, wherein each of the at least two transport conduits along the second base pipe extends substantially along the length of the second base pipe.
10. The method of claim 1, wherein each of the at least two transport conduits along the first base pipe extends substantially along the length of the first base pipe, but one of the at least two transport conduits has a nozzle intermediate the first and second ends of the first base pipe.

11. The method of claim 10, wherein:
 - the nozzle comprises a valve; and
 - the method further comprises adjusting the valve to increase or decrease fluid flow through the valve.
12. The method of claim 1, wherein at least one of the at least two transport conduits along the first base pipe has an outlet end intermediate the first and second ends of the first base pipe.
13. The method of claim 1, wherein the at least two transport conduits have different inner diameters.
14. The method of claim 1, further comprising:
 - producing hydrocarbon fluids through the base pipes of the first and second base pipes from at least one interval along the wellbore, wherein producing hydrocarbon fluids causes hydrocarbon fluids to travel from the secondary flow path to the primary flow path.
15. The method of claim 1, further comprising:
 - injecting a fluid through the base pipes and into the wellbore along at least one interval, wherein injecting the fluid causes fluids to travel from the primary flow path to the secondary flow path.
16. The method of claim 15, wherein the fluid comprises a gas, an aqueous solution, steam, diluent, solvent, fluid loss control material, viscosified gel, viscoelastic fluid, chelating agent, acid, or a chemical consolidation agent.
17. The method of claim 1, further comprising:
 - placing a plug into the wellbore downstream from the first and second base pipes.
18. The method of claim 1, further comprising:
 - providing a packer assembly comprising:
 - at least one sealing element,
 - an inner mandrel, and
 - transport conduits extending substantially along the inner mandrel; and

operatively connecting the packer assembly to the first end of the first base pipe such that (i) the inner mandrel of the packer assembly is in fluid communication with the bores of the base pipes, and (ii) the transport conduit of the packer assembly are in fluid communication with the transport conduits of the base pipes;

and wherein the step of running the base pipes and connected joint assembly into the wellbore further comprises running the packer assembly into the wellbore; and

the method further comprises setting the at least one sealing element into engagement with the surrounding wellbore.

19. The method of claim 18, wherein:

the packer assembly comprises a mechanically set packer; and

setting the sealing element comprises setting the mechanically-set packer into engagement with the surrounding open-hole formation.

20. The method of claim 1, wherein the transport conduits of the load sleeve and the transport conduits of the torque sleeve each defines about six transport conduits placed within and radially around its corresponding tubular body.

21. The method of claim 1, wherein:

the coupling assembly further comprises an inflow control device adjacent an opening in the flow port; and

the method further comprises adjusting the inflow control device to increase or decrease fluid flow through the flow port.

22. The method of claim 21, wherein the inflow control device is controlled by a radio frequency signal, a mechanical shifting tool, or hydraulic pressure.

23. A joint assembly residing within a wellbore, comprising:

a first base pipe and a second base pipe connected in series, each base pipe comprising:

a tubular body having a first end, a second end and a bore there between forming a primary flow path for fluids; and

at least two transport conduits along an outer diameter configured to transport fluids as a secondary flow path; and

a coupling assembly operatively connecting the second end of the first base pipe to the second end of the first base pipe, wherein the coupling assembly comprises a manifold that places respective transport conduits of the base pipes in fluid communication, and a flow port adjacent the manifold that places the primary flow path in fluid communication with the secondary flow path along a portion of the wellbore.

24. The joint assembly of claim 23, wherein the coupling assembly comprises:

a load sleeve mechanically connected proximate to the first end of the second base pipe;

a torque sleeve mechanically connected proximate to the second end of the first base pipe; and

an intermediate coupling joint comprising a main tubular body defining a bore in fluid communication with the primary flow path, the main tubular body having a first end and a second end, wherein the first end is threadedly connected to the second end of the first base pipe, and the second end is threadedly connected to the first end of the second base pipe.

25. The joint assembly of claim 24, wherein:

the load sleeve and the torque sleeve each comprises:

a tubular body defining an inner bore therein in fluid communication with the primary flow path, and

transport conduits disposed longitudinally along the tubular body in fluid communication with the secondary flow path; and

the coupling joint further comprises:

a coaxial sleeve positioned around the tubular body, the sleeve forming an annular region between the tubular body and the sleeve, with the annular region defining the manifold, and the manifold placing the transport conduits of the load sleeve and of the torque sleeve in fluid communication.

26. The joint assembly of claim 25, wherein the flow port comprises (i) a through opening in the tubular body of the coupling joint, (ii) a through-opening in the second end of the first tubular body, (iii) a through-opening in the first end of the second tubular body, or (iv) combinations thereof.

27. The joint assembly of claim 26, wherein the tubular bodies comprise perforated base pipes.
28. The joint assembly of claim 26, wherein the base pipes comprise a series of joints threadedly connected to form the primary flow path.
29. The joint assembly of claim 26, wherein the tubular bodies comprise blank pipes having a filter medium radially around the pipes and along a substantial portion of the pipes so as to form a sand screen.
30. The joint assembly of claim 26, wherein the filtering medium of each sand screen comprises a wire-wrapped screen, a slotted liner, a ceramic screen, a membrane screen, an expandable screen, a sintered metal screen, a wire-mesh screen, a shape memory polymer, or a pre-packed solid particle bed.
31. The joint assembly of claim 26, wherein each of the at least two transport conduits along the second base pipe extends substantially along the length of the second base pipe.
32. The joint assembly of claim 26, wherein each of the at least two transport conduits along the first base pipe extends substantially along the length of the first base pipe, but one of the at least two transport conduits has a nozzle intermediate the first and second ends of the first base pipe.
33. The joint assembly of claim 32, wherein at least one of the at least two transport conduits along the first base pipe has an outlet end intermediate the first and second ends of the first base pipe.
34. The joint assembly of claim 26, further comprising:
a packer assembly comprising:
at least one sealing element,
an inner mandrel, and
transport conduits extending substantially along the inner mandrel; and
wherein the packer assembly is operatively connected to the first end of the first base pipe such that (i) the inner mandrel of the packer assembly is in fluid communication with the

bores of the base pipes, and (ii) the transport conduit of the packer assembly are in fluid communication with the transport conduits of the base pipes.

35. The joint assembly of claim 34, wherein the packer assembly comprises a mechanically set packer, a swellable packer, or a combination thereof.

36. The joint assembly of claim 26, wherein:
the coupling joint further comprises an inflow control device adjacent an opening in the flow port configured to increase or decrease fluid flow through the flow port.

37. The joint assembly of claim 26, wherein the flow port defines an inflow control device.

38. The joint assembly of claim 26, wherein:
opposing ends of the co-axial sleeve have respective shoulders that land on the load sleeve and the torque sleeve; and
the joint assembly further comprises sealing rings to provide a fluid seal of the annular region around the respective shoulders.

39. The joint assembly of claim 38, wherein:
the load sleeve is mechanically connected to the second base pipe by means of bolts;
the torque sleeve is mechanically connected to the first base pipe by means of bolts;
and
the coaxial sleeve is mechanically connected to the main tubular body by means of bolts, such that the manifold is in fixed position.
