IMMUNOGENIC COMPOSITIONS AGAINST HELICOBACTER
INFECTION, POLYPEPTIDES FOR USE IN THE COMPOSITIONS
AND NUCLEIC ACID SEQUENCES ENCODING SAID POLYPEPTIDES

The present invention relates to immunogenic compositions for inducing protective antibodies against Helicobacter spp. infection. It also relates to proteinaceous material derived from Helicobacter, and to nucleic acid sequences encoding them. Antibodies to these proteinaceous materials are also included in the invention.

H. pylori is a microorganism which infects human gastric mucosa and is associated with active chronic gastritis. It has been shown to be an aetiological agent in gastroduodenal ulceration (Peterson, 1991) and two recent studies have reported that persons infected with H. pylori had a higher risk of developing gastric cancer (Nomura et al, 1991 ; Parsonnet et al, 1991).

In vivo studies of the bacterium and, consequently, work on the development of appropriate preventive or therapeutic agents has been severely hindered by the fact that Helicobacter pylori only associates with gastric-type epithelium from very few animal hosts, none of which are suitable for use as laboratory models.

A mouse model of gastric colonisation has been developed using a helical bacterium isolated from cat gastric mucus (Lee et al, 1988, 1990) and identified as a member of the genus Helicobacter. It has been named H. felis (Paster et al, 1990).

To date, only limited information concerning H. felis and the extent of its similarities and

differences with H. pylori, is available. The reliability of the mouse model for the development of treatments for H. pylori infection is therefore uncertain. Recently, it was shown that H. pylori urease is a protective antigen in the H. felis / mouse model (Davin et al, 1993 ; Corthesy-Theulaz et al, 1993).

It is therefore an aim of the present invention to provide therapeutic and preventive compositions for use in Helicobacter infection, which furthermore can be tested in laboratory animals.

It is known that H. pylori expresses urease activity and that urease plays an important role in bacterial colonisation and mediation of certain pathogenic processes (Ferrero and Lee, 1991 ; Hazel et al, 1991).

The genes coding for the urease structural polypeptides of H. pylori (URE A, URE B) have been cloned and sequenced (Labigne et al, 1991 ; and French Patent Application FR 8813135), as have the genes coding the "accessory" polypeptides necessary for urease activity in H. pylori (International patent application WO 93/07273).

Attempts have been made to use nucleic acid sequences from the H. pylori urease gene cluster as probes to identify urease sequences in H. felis. However, none of these attempts have been successful. Furthermore, the establishment and maintenance of H. felis cultures in vitro is extremely difficult, and the large quantities of nucleases present in the bacteria complicates the extraction of DNA.

The present inventors have however, succeeded in cloning and sequencing the genes of the urease structural polypeptides of H. felis, and of the accessory polypeptides. This has enabled, in the

context of the invention, the comparison of the amino-acid sequence data for the H. felis ure gene products with that for Helicobacter pylori, and a high degree of conservation between the urease sub-units has been found. An immunological relationship between the 2 ureases exists, and protective antibodies to Helicobacter infection can be induced using the urease sub-units or fragments thereof as immunogens.

Indeed, to elucidate the efficiency of individual urease subunits to act as mucosal immunogens, the genes encoding the respective urease subunits (UreA and UreB) of Helicobacter pylori and Helicobacter felis have been cloned in an expression vector (pMAL), and expressed in Escherichia coli cells as translational fusion proteins. The recombinant UreA and UreB proteins have been purified by affinity and anion exchange chromatography techniques, and have predicted molecular weights of approximately 68 and 103 kDa, respectively. Western blotting studies indicated that the urease components of the fusion proteins are strongly immunogenic and are specifically recognized by polyclonal rabbit anti-Helicobacter sera. Orogastric immunization of mice with 50 µg of recombinant H. felis UreB, administered in combination with a mucosal adjuvant (cholera toxin), protected 60 % (n = 7 ; p < 0.005) of mice from gastric colonization by H. felis bacteria at over 4 months. This compared with a value of 25 % (n = 8 ; p > 0.05) for the heterologous H. pylori UreB antigen. For the first time, a recombinant subunit antigen has been shown to induce an immunoprotective response against gastric Helicobacter infection.

The inventors have also identified, in the context of the invention, new Heat Shock Proteins or chaperonins, in Helicobacter, which have an enhancing

effect on urease activity. Use of the chaperonins in an immunogenic composition may induce therefore an enhancement of protection.

Indeed, the genes encoding each of the HspA and HspB polypeptides of Helicobacter pylori have been cloned, expressed independently as fused proteins to the Maltose-Binding-Protein (MBP), and purified on a large scale. These proteins have been used as recombinant antigens to immunize rabbits, and in Western immunoblotting assays as well as ELISA to determine their immunogenicity in patients infected with HP (HP+). The MBP-HspA and MBP-HspB fusion proteins have been shown to retain their antigenic properties. Comparison of the humoral immune response against HspA and/or HspB in (HP+) patient sera demonstrated that not only HspB but also HspA was recognized by (HP+) patient sera (29/38 and 15/38, respectively). None of the 14 uninfected patients had antibodies reacting with the Hsps.

The present invention concerns an immunogenic composition capable of inducing antibodies against Helicobacter infection characterised in that it comprises :

i) at least one sub-unit of a urease structural polypeptide from Helicobacter pylori, or a fragment thereof, said fragment being recognised by antibodies reacting with Helicobacter felis urease, and/or at least one sub-unit of a urease structural polypeptide from Helicobacter felis, or a fragment thereof, said fragment being recognised by antibodies reacting with Helicobacter pylori urease ;

ii) and/or a Heat Shock protein (HSP), or chaperonin, from Helicobacter, or a fragment of said protein.

This Sheet Has Been Replaced

Preferably, the immunogenic composition is capable of inducing protective antibodies.

According to a preferred embodiment, the immunogenic composition of the invention contains, as the major active ingredient, at least one sub-unit of a urease structural polypeptide from Helicobacter pylori and/or Helicobacter felis. The expression "urease structural polypeptide" signifies, in the context of the present invention, the enzyme of Helicobacter pylori or Helicobacter felis probably a major surface antigen composed of two repeating monomeric sub-units, a major sub-unit (product of the ure B gene) and a minor sub-unit, product of the ure A gene and which, when complemented by the presence of the products of the accessory genes of the urease gene cluster, are responsible for urease activity i.e. the hydrolysis of urea to liberate NH_4^+ in the two Helicobacter species. It is to be understood that in the absence of the accessory gene products, the urease structural polypeptides do not exhibit enzymatic activity, but are recognised by antibodies reacting with H. felis or H. pylori urease.

The term "immunogenic composition" signifies, in the context of the invention, a composition comprising a major active ingredient as defined above, together with any necessary ingredients to ensure or to optimise an immunogenic response, for example adjuvants, such as mucosal adjuvant, etc...

The Helicobacter pylori urease structural polypeptide has been described and sequenced by Labigne et al, 1991. The polypeptide described in this paper is particularly appropriate for use in the composition of the present invention. However, variants showing functional homology with this published sequence may be used, which comprise amino-

acid substitutions, deletions or insertions provided that the immunological characteristics of the polypeptide in so far as its cross-reactivity with anti-Helicobacter felis urease antibodies is concerned, are maintained. Generally speaking, the polypeptide variant will show a homology of at least 75% and preferably about 90% with the included sequence.

A fragment of the Helicobacter pylori urease structural polypeptide may also be used in the immunogenic composition of the invention, provided that the fragments are recognised by antibodies reacting with Helicobacter felis urease. Such a fragment will generally be comprised of at least 6 amino-acids, for example, from 6 to 100 amino-acids, preferably about 20-25. Advantageously, the fragment carries epitopes unique to Helicobacter.

Nucleic acid and amino-acid sequences may be interpreted in the context of the present invention by reference to figures 11 and 12, showing the genetic code and amino-acid abbreviations respectively.

The Helicobacter felis urease structural polypeptide suitable for use in the present invention is preferably that encoded by part of the plasmid pILL205 (deposited at the CNCM on 25th August 1993, under number : CNCM I-1355), and whose amino-acid sequence is shown in figure 3 (subunits A and B). Again, a variant of this polypeptide comprising amino-acid substitutions, deletions or insertions with respect to the figure 3 sequence may be used provided that the immunological cross-relationship with Helicobacter pylori urease is maintained. Such a variant normally exhibits at least 90 % homology or identity with the figure 3 sequence. An example of such variants are the urease A and B sub-units from

Helicobacter heilmannii (Solnick et al, 1994), shown to have 80 % and 92 % identity with the H. felis urease A and B sub-units, respectively.

Fragments of this urease or variants may be used in the immunogenic composition provided that the fragments are recognised by antibodies reacting with Helicobacter pylori urease. Again, the length of such a fragment is usually at least 6 amino-acids, for example from 6 to 100, preferably about 20 to 25. Preferably, the fragment carries epitopes unique to Helicobacter.

If variants or fragments of the native urease sequences are employed in the immunogenic composition of the invention, their cross-reactivity with antibodies reacting with urease from the other Helicobacter species can be tested by contacting the fragment or the variant with antibodies, preferably polyclonal raised to either the native or the recombinant urease or, alternatively, to whole Helicobacter. Preferably, the variants and fragments give rise to antibodies which are also capable of reacting with H. heilmannii urease. Cross protection to infection by H. heilmannii is therefore also obtained by the immunogenic composition of the invention.

The use of fragments of the urease structural genes is particularly preferred since the immunological properties of the whole polypeptide may be conserved whilst minimizing risk of toxicity.

The active component of the immunogenic composition of the invention may be comprised of one sub-unit only of the urease structural polypeptide, that is either sub-unit A or sub-unit B products of the ure A and ure B genes respectively. Compositions comprising only the urease sub-unit Ure B, of either

H. pylori or H. felis, or variants and fragments as defined above, are particularly advantageous. Most preferred are homologous systems wherein the urease sub-unit particularly sub-unit B, is derived from the organism against which protection is sought, e.g. H. felis sub-unit B against H. felis infection. However, the composition may contain both A and B sub-units, which are normally present as distinct polypeptides. However, it is possible, when the polypeptide is produced by recombinant means, to use a fusion protein comprising the entire sequences of the A and B gene products by the suppression of the stop-codon separating the two adjacent coding sequences.

The urease component of the immunogenic composition, whether sub-unit A or sub-unit B, may be used in the form of translational fusion proteins, for example with the Maltose-Binding-Protein (MBP). Other suitable fusions are exemplified in International Patent Application WO 90/11360. Another example of a suitable fusion protein is the "QIAexpress" system commercialised by QIAGEN, USA, which allows the 6xHis tag sequence to be placed at the 5' or 3' end of the protein coding sequence. The use of the active ingredients in the form of fusion proteins is however, entirely optional.

According to a further preferred embodiment, the immunogenic composition of the invention may comprise in addition to or instead of the urease structural polypeptide defined above, a Heat Shock Protein also known as a "chaperonin" from Helicobacter. These chaperonins have been elucidated by the inventors in the context of the present invention. Preferably, the chaperonin is from Helicobacter pylori. Such an HSP may be the urease-associated HSP A or HSP B or a mixture of the two, having the amino-acid sequence

illustrated in figure 6. These polypeptides are encoded by the plasmid pILL689 (deposited at CNCM on 25th August 1993, under number : CNCM I-1356). Particularly preferred is the H. pylori HSP-A protein, either alone or in combination with Hsp-B.

It is also possible to use, as HSP component, according to the invention, a polypeptide variant in which amino-acids of the figure 6 sequence have been replaced, inserted or deleted, the said variant normally exhibiting at least 75 %, and preferably at least 85 % homology with the native HSP. The variants preferably exhibit at least 75 %, for example at least 85 % identity with the native Hsp.

The variants may further exhibit functional homology with the native polypeptide. In the case of the HSP components, "functional homology" means the capacity to enhance urease activity in a micro-organism capable of expressing active urease, and/or the capacity to block infection by Helicobacter, particularly H. felis and H. pylori. The property of enhancing urease activity may be tested using the quantitative urease activity assay described below in the examples. Fragments of either or both of the HSP A and HSP B polypeptides preferably having at least 6 amino-acids, may be used in the composition. The fragments or variants of the HSP component used in the immunogenic composition of the invention are preferably capable of generating antibodies which block the urease enhancing effect normally exhibited by the HSPs. This property is also tested using the quantitative assay described in the examples. The presence of the chaperonins in the composition enhances the protection against Helicobacter pylori and felis.

This Sheet Has Been Replaced

The Hsp component of the immunogenic composition, whether HspA or HspB can be used in the form of a translational fusion protein, for example with the Maltose-Binding-Protein (MBP). As for the urease component, other suitable fusion partners are described in International Patent Application WO 90/11360. The "QIAexpress" system of QIAGEN, USA, may also be used. Again, the use of the proteins in the form of fusion proteins is entirely optional.

According to the invention therefore the immunogenic composition may comprise either a urease structural polypeptide as defined above, or a Helicobacter Hsp, particularly HspA or a combination of these immunogens.

According to a preferred embodiment, the immunogenic composition comprises, as urease component, both the A and B sub-units of both Helicobacter felis (i.e. without H. pylori urease) together with the HSP A and HSP B of Helicobacter pylori. Alternatively, the A and B sub-units of the Helicobacter felis urease may be used together with those of H. pylori, but without chaperonin component.

The immunological cross-reactivity between the ureases of the two different Helicobacter species enables the use of one urease only in the composition, preferably that of Helicobacter felis. The protective antibodies induced by the common epitopes will however be active against both Helicobacter pylori and Helicobacter felis. It is also possible that the composition induce protective antibodies to other species of Helicobacter, if the urease polypeptide or fragment carries epitopes occurring also on those other species.

The composition of the invention is advantageously used as an immunogenic composition or a

vaccine, together with physiologically acceptable excipients and carriers and, optionally, with adjuvants, haptens, carriers, stabilizers, etc. Suitable adjuvants include muranmyl dipeptide (MDP), complete and incomplete Freund's adjuvants (CFA and IFA) and alum. The vaccine compositions are normally formulated for oral administration.

The vaccines are preferably for use in man, but may also be administered in non-human animals, for example for veterinary purposes, or for use in laboratory animals such as mice, cats and dogs.

The immunogenic compositions injected into animals raises the synthesis in vivo of specific antibodies, which can be used for therapeutic purposes, for example in passive immunity.

The invention also relates to the proteinaceous materials used in the immunogenic composition and to proteinaceous material encoded by the urease gene clusters other than the A and B urease structural sub-units. "Proteinaceous material" means any molecule comprised of chains of amino-acids, eg. peptides, polypeptides or proteins, fusion or mixed proteins (i.e. an association of 2 or more proteinaceous materials, all or some of which may have immunogenic or immunomodulation properties), either purified or in a mixture with other proteinaceous or non-proteinaceous material. "Polypeptide" signifies a chain of amino-acids whatever its length and englobes the term "peptide". The term "fragment" means any amino-acid sequence shorter by at least one amino-acid than the parent sequence and comprising a length of amino-acids e.g. at least 6 residues, consecutive in the parent sequence.

The peptide sequences of the invention, may for example, be obtained by chemical synthesis, using a

technique such as the Merrifield technique and synthesiser of the type commercialised by Applied Biosystems.

In particular, the invention relates to proteinaceous material characterised in that it comprises at least one of the Helicobacter felis polypeptides encoded by the urease gene cluster of the plasmid pILL205 (CNCM I-1355), including the structural and accessory urease polypeptides, or a polypeptide having at least 90 % homology with said polypeptides, or a fragment thereof. Of particular interest are the gene products of the ure A and ure B genes, as illustrated in figure 3, or a variant thereof having at least 90 % homology or a fragment having at least 6 amino-acids. The fragments and the variants are recognised by antibodies reacting with Helicobacter pylori urease.

Amongst the polypeptides encoded by the accessory genes of the urease gene cluster, is the gene product of ure I, as illustrated in figure 9, which also forms part of the invention. Also included is a variant of the ure I product having at least 75 % homology, preferably at least 85 %, or a fragment of the gene product or of the variant having at least 6 amino-acids. The variant preferably has the capacity to activate the ure A and ure B gene products in the presence of the remaining urease accessory gene products. This functional homology can be detected by using the following test : 10⁹ bacteria containing the ure I gene product variant are suspended in 1 ml of urea-indole medium and incubated at 37° C. The hydrolysis of the urea leads to the release of ammonium, which increases pH and induces a colour change from orange to fuschia-red. The observation of such a colour change demonstrates that the variant of

the ure I gene product under test is capable of activating the ure A and B gene products.

It is also possible that a fragment of the ure I gene product, if it has a length of, for example, at least 70 or 100 amino-acids, may also exhibit this functional homology with the entire polypeptide.

The fragments of ure I polypeptide or of the variant preferably are capable of inducing the formation of antibodies which block the urease maturation process. In other words, the fragments bear epitopes which play a decisive role in the interaction between the ure I and ure A / ure B gene products.

The invention also relates to the proteinaceous material comprising at least one of the Heat Shock Proteins or chaperonins of Helicobacter pylori or a fragment thereof. Particularly preferred are the HSP A and HSP B polypeptides as illustrated in figure 6 or a polypeptide having at least 75 %, and preferably at least 80 or 90 %, homology or identity with the said polypeptide. A particularly preferred fragment of the Helicobacter pylori HSP A polypeptide is the C-terminal sequence :

G S C C H T G N H D H K H A K E H E A C C H D H K K H

or a sub-fragment of this sequence having at least 6 consecutive amino-acids. This C-terminal sequence is thought to act as a metal binding domain allowing binding of, for example, nickel.

The proteinaceous material of the invention may also comprise or consist of a fusion or mixed protein including at least one of the sub-units of the urease structural polypeptide of H. pylori and/or of H. felis, or fragments or variants thereof as defined above. Particularly preferred fusion proteins are the

Mal-E fusion proteins and QIAexpress system fusion proteins (QIAGEN, USA) as detailed above. The fusion or mixed protein may include, either instead of in addition to the urease sub-unit, a Heat Shock Protein, or fragment or variant thereof, as defined above.

The invention also relates to monoclonal or polyclonal antibodies to the proteinaceous materials described above. More particularly, the invention relates to antibodies or fragments thereof to any one of the Helicobacter felis polypeptides encoded by the urease gene cluster of the plasmid pILL205 (CNCM I-1355) including the structural and accessory urease polypeptides that is, structural genes ure A and ure B and the accessory genes known as ure C, ure D, ure E, ure F, ure G, ure H and ure I. The antibodies may also be directed to a polypeptide having at least 90 % homology with any of the above urease polypeptides or to a fragment thereof preferably having at least 6 amino-acids. The antibodies of the invention may specifically recognise Helicobacter felis polypeptides expressed by the urease gene cluster. In this case, the epitopes recognised by the antibodies are unique to Helicobacter felis. Alternatively, the antibodies may include or consist of antibodies directed to epitopes common to Helicobacter felis urease polypeptides and to Helicobacter pylori urease polypeptides. If the antibodies recognise the accessory gene products, it is particularly advantageous that they cross-react with the Helicobacter pylori accessory gene product. In this way, the antibodies may be used in therapeutic treatment of Helicobacter pylori infection in man, by blocking the urease maturation process.

Particularly preferred antibodies of the invention recognise the Helicobacter felis ure A

and/or ure B gene products, that is the A and B urease sub-units. Advantageously, these antibodies also cross-react with the Helicobacter pylori A and B urease sub-units, but do not cross-react with other ureolytic bacteria. Such antibodies may be prepared against epitopes unique to Helicobacter (see figure 4), or alternatively, against the whole polypeptides followed by screening out of any antibodies reacting with other ureolytic bacteria.

The invention also concerns monoclonal or polyclonal antibodies to the HSPs or fragments thereof, particularly to the HSP A and/or HSP B protein illustrated in figure 6. Polypeptides having at least 75 %, and preferably at least 80 %, or 90 % homology with the HSPs may also be used to induce antibody formation. These antibodies may be specific for the Helicobacter pylori chaperonins or, alternatively, they may cross-react with GroEL-like proteins or GroES-like proteins from bacteria other than Helicobacter, depending upon the epitopes recognised. Figure 7 shows the homologous regions of HSP A and HSP B with GroES-like proteins and GroEL-like proteins respectively from various bacteria. Particularly preferred antibodies are those specific for either the HSP A or HSP B chaperonins or those specifically recognising the HSP A C-terminal sequence having the metal binding function. Again, use of specific fragments for the induction of the antibodies ensures production of Helicobacter-specific antibodies.

The antibodies of the invention may be prepared using classical techniques. For example monoclonal antibodies may be produced by the hybridoma technique or by known techniques for the preparation of human antibodies, or by the technique described by Marks et

al (Journal of Molecular Biology, 1991, 222, p 581-597).

The invention also includes fragments of any of the above antibodies produced by enzyme digestion. Of particular interest are the Fab and F(ab')₂ fragments. Also of interest are the Facb fragments.

The invention also relates to purified antibodies or serum obtained by immunisation of an animal, e.g. a mammal, with the immunogenic composition, the proteinaceous material or fragment, or the fusion or mixed protein of the invention, followed by purification of the antibodies or serum. Also concerned is a reagent for the in vitro detection of H. pylori infection, containing at least these antibodies or serum, optionally with reagents for labelling the antibodies e.g. anti-antibodies etc.

The invention further relates to nucleic acid sequences coding for any of the above proteinaceous materials including peptides. In particular, the invention relates to a nucleic acid sequence characterised in that it comprises :

i) a sequence coding for the Helicobacter felis urease and accessory polypeptides as defined above, and a sequence coding for the HSP of H. pylori as defined above ;

or ii) a sequence complementary to sequence (i) ;

or iii) a sequence capable of hybridizing to sequence (i) or (ii) under stringent conditions ;

or iv) a fragment of any of sequences (i), (ii) or (iii) comprising at least 10 nucleotides.

Preferred nucleic acid sequences are those comprising all or part of the sequence of plasmid pIL205 (CNCM I-1355), for example the sequence of Figure 3, in particular that coding for the gene product of ure A and for ure B or the sequence of

Figure 9 (Ure I), or a sequence capable of hybridising with these sequences under stringent conditions, or a sequence complementary to these sequences, or a fragment comprising at least 10 consecutive nucleotides of these sequences.

Other preferred sequences are those comprising all or part of the sequence of plasmid pILL689 (CNCM I-1356), for example the sequence of figure 6, in particular that coding for HSP A and/or HSP B, or a sequence complementary to this sequence, or a sequence capable of hybridizing to this sequence under stringent conditions, or a fragment thereof.

High stringency hybridization conditions in the context of the invention are the following :

- 5 x SSC ;
- 50 % formamide at 37°C ;

or :

- 6 x SSC ;
- Denhard medium at 68°C.

The sequences of the invention also include those hybridizing to any of sequences (i), (ii) and (iii) defined above under non-stringent conditions, that is :

- 5 x SSC ;
- 0.1 % SDS ;
- 30 or 40 % formamide at 42°C, preferably 30 %.

The term "complementary sequences" in the context of the invention signifies "complementary" and "reverse" or "inverse" sequences.

The nucleic acid sequences may be DNA or RNA.

The sequences of the invention may be used as nucleotide probes in association with appropriate labelling means. Such means include radio-active isotopes, enzymes, chemical or chemico-luminescent markers, fluoro-chromes, haptens, or antibodies. The

markers may optionally be fixed to a solid support, for example a membrane, or particles.

As a preferred marker, radio-active phosphorous (^{32}P) is incorporated at the 5'-end of the probe sequence. The probes of the invention comprise any fragment of the described nucleic acid sequences and may have a length for example of at least 45 nucleotides, for example 60, 80 or 100 nucleotides or more. Preferred probes are those derived from the ure A, ure B, ure I, HSP A and HSP B genes.

The probes of the invention may be used in the in vitro detection of Helicobacter infection in a biological sample, optionally after a gene amplification reaction. Most advantageously, the probes are used to detect Helicobacter felis or Helicobacter pylori, or both, depending on whether the sequence chosen as the probe is specific to one or the other, or whether it can hybridise to both. Generally, the hybridisation conditions are stringent in carrying out such a detection.

The invention also relates to a kit for the in vitro detection of Helicobacter infection, characterised in that it comprises :

- a nucleotide probe according to the invention, as defined above ;
- an appropriate medium for carrying out a hybridisation reaction between the nucleic acid of Helicobacter and the probe ;
- reagents for the detection of any hybrids formed.

The nucleotide sequences of the invention may also serve as primers in a nucleic acid amplification reaction. The primers normally comprise at least 10 consecutive nucleotides of the sequences described above and preferably at least 18. Typical lengths are

from 25 to 30 and may be as high as 100 or more consecutive nucleotides. Such primers are used in pairs and are chosen to hybridize with the 5' and 3'-ends of the fragment to be amplified. Such an amplification reaction may be performed using for example the PCR technique (European patent applications EP200363, 201184 and 229701). The Q- β -replicase technique (Biotechnology, vol. 6, Oct. 1988) may also be used in the amplification reaction.

The invention also relates to expression vectors characterised in that they contain any of the nucleic acid sequences of the invention. Particularly preferred expression vectors are plasmids pILL689 and pILL205 (CNCM I-1356 and CNCM I-1355, respectively). The expression vectors will normally contain suitable promoters, terminators and marker genes, and any other regulatory signals necessary for efficient expression.

The invention further relates to prokaryotic or eukaryotic host cells stably transformed by the nucleic acid sequences of the invention. As examples of hosts, mention may be made of higher eukaryotes such as CHO cells and cell-lines ; yeast, prokaryotes including bacteria such as E. coli e.g. E. coli HB 101 ; Mycobacterium tuberculosis ; viruses including baculovirus and vaccinia. Usually the host cells will be transformed by vectors. However, it is also possible within the context of the invention, to insert the nucleic acid sequences by homologous recombination, using conventional techniques.

By culturing the stably transformed hosts of the invention, the Helicobacter urease polypeptide material and, where applicable, the HSP material can be produced by recombinant means. The recombinant proteinaceous materials are then collected and purified. Pharmaceutical compositions are prepared by

combining the recombinant materials with suitable excipients, adjuvants and optionally, any other additives such as stabilizers.

The invention also relates to plasmids pILL920 (deposited at CNCM on 20.07.1993, under accession number I-1337) and pILL927 (CNCM I-1340, deposited on 20.07.1993) constructed as described in the examples below.

Different aspects of the invention are illustrated in the figures :

Figure 1 :

Transposon mutagenesis and sequencing of pILL205. Linear restriction maps of recombinant cosmid pILL199 and recombinant plasmid pILL205 (and the respective scale markers) are presented. Numbers in parentheses indicate the sizes of H.felis DNA fragments inserted into one of the cloning vectors (pILL575 or pILL570, respectively). The "plus" and "minus" signs within circles correspond to the insertion sites of the MiniTn3-Km transposon in pILL205 ; "plus" signs indicate that the transposon did not inactivate urease expression, whereas negative signs indicate that urease expression was abolished. The letters refer to mutant clones which were further characterised for quantitative urease activity and for the synthesis of urease gene products. The location of the structural urease genes (ure A and ure B) on pILL205 are represented by boxes, the lengths of which are proportional to the sizes of the respective open-reading frames. The arrows refer to the orientation of transcription. The scale at the bottom of the figure indicates the sizes (in kilobases) of the HindIII and PstI restriction fragments. Restriction sites are

represented as follows : B, BamHI ; Pv, PvuII ; Bg, BglII ; E, EcoRI ; H, HindIII ; C, ClaI ; Ps, PstI. Letters within parentheses indicate that the sites originated from the cloning vector.

Figure 2 :

Western blot analysis of whole-cell extracts of E. coli HB101 cells harbouring recombinant plasmids were reacted with rabbit polyclonal antiserum (diluted 1:1, 1000) raised against H. felis bacteria. A) extracts were of E. coli cells harbouring : plasmid vector pILL570 (lane 1) ; recombinant plasmid pILL205 (lane 2) ; and pILL205 derivative plasmids disrupted in loci "a", "b", "c", "d", and "e" (lanes 3-7). B) Extracts were of E. coli cells harbouring : recombinant plasmid pILL753 containing the H. pylori ure A and ure B genes (Labigne et al., 1991) (lane 1) ; and pILL205 derivative plasmids disrupted in loci "f", "g", "h", and "i" (lanes 2-5). The small arrow heads indicate polypeptides of approximately 30 and 66 kilodaltons which represent putative Ure A and Ure B gene products of H. felis. The large arrow heads in panel B indicate the corresponding gene products of H. pylori which cross-reacted with the anti-H. felis serum. The numbers indicate the molecular weights (in thousands) of the protein standards.

Figure 3 :

Nucleotide sequence of the H. felis structural urease genes. Numbers above the sequence indicate the nucleotide positions as well as the amino acid position in each of the two Ure A and Ure B polypeptides. Predicted amino acid sequences for Ure A (bp 43 to 753) and Ure B (766 to 2616) are shown below

the sequence. The putative ribosome-binding site (Shine-Dalgarno sequence, SD) is underlined.

Figure 4 :

Comparison of sequences for the structural urease genes of H. felis to : a) the sequence of the two subunits of H. pylori urease (Labigne et al., 1991) ; b) the sequence of the three subunits of Proteus mirabilis urease (Jones and Mobley, 1989) ; c) the sequence of the single subunit of jack bean urease. Gaps (shown by dashes) have been introduced to ensure the best alignment. *, amino acids identical to those of the H. felis sequence ; =, amino-acids shared by the various ureases ; ., amino-acids unique to the Helicobacter ureases. The percentages relate to the number of amino acids that are identical to those of the H. felis urease subunits. Signification of the one-letter and three-letter amino-acid abbreviations.

Figure 13 :

Purification of H. pylori UreA-MBP recombinant protein using the pMAL expression vector system. Extracts from the various stages of protein purification were migrated on a 10 % resolving SDS-polyacrylamide gel. Following electrophoresis, the gel was stained with Coomassie blue. The extracts were : 1) non-induced cells ; 2) IPTG-induced cells ; French press lysate of induced cell extract ; 5) eluate from amylose resin column ; 6) eluate from anion exchange column (first passage) ; 7) eluate from anion exchange column (second passage) ; 8) SDS-PAGE standard marker proteins.

Figure 14 :

Recognition of UreA recombinant fusion proteins by polyclonal rabbit anti-Helicobacter sera. Protein extracts of maltose-binding protein (MBP, lane 1), H. felis UreA-MBP (lane 2), and H. pylori UreA-MBP (lane 3) were Western Blotted using rabbit polyclonal antisera (diluted 1 : 5000) raised against whole-cell extracts of H. pylori and H. felis. The purified fusion proteins are indicated by an arrow. Putative degradation products of the proteins are shown by an asterisk.

Figure 15 :

Recognition of UreB recombinant fusion proteins by rabbit antisera raised against purified homologous

and heterologous UreB proteins. Nitrocellulose membranes were blotted with the following extracts : 1) standard protein markers ; 2) H. felis UreA-MBP ; 3) MBP ; 4) H. pylori UreA-MBP. The membranes were reacted with polyclonal rabbit antisera (diluted 1 : 5000) raised against MBP-fused H. pylori and H. felis Ure B sub-units, respectively. The molecular weights of standard proteins are presented on the left-hand side of the blots.

Figure 16 :

Western blot analysis of H. pylori and H. felis whole-cell extracts with antisera raised against purified UreB MBP-fused recombinant proteins. SDS-PAGE whole extracts of H. Felis (lane 1) and H. pylori (lane 2) cells were reacted with polyclonal rabbit antisera raised against purified H. pylori UreB and H. felis UreB MBP-fused proteins (sera diluted 1 : 5000). The difference in gel mobility of the respective non-recombinant UreB sub-units of H. felis and H. pylori can be seen. The numbers on the left refer to the molecular weights of standard marker proteins.

Figure 17 :

SDS-PAGE analysis of material eluted from the amylose column (lanes 2 and 3) or from the Ni-NTA column following elution : with buffer E (pH 4.5), lanes 4 and 5 ; or buffer C (pH 6.3), lanes 6 and 7. Material eluted from a lysate of MC1061 (PILL933) (lanes 2, 3, 5 and 7) and material eluted from a lysate of MC1061 (PMAL-c2) (lanes 4 and 6). Lane 3 contains the same material as in lane 2 except that it was resuspended in buffer E, thus demonstrating that buffer E is responsible for dimer formation of the MBP-HspA subunit, as seen in lanes 3 and 5.

Figure 18 :

Serum IgG responses to MBP (bottom), MBP-HspA (top) and MBP-HspB (middle) of 28 H. pylori infected patients (squares, left) and 12 uninfected patients (circles, right). The optical density of each serum in the ELISA assay described in Experimental procedures was read at 492 nm, after a 30 mn incubation. The sizes of the symbols are proportional to the number of sera giving the same optical density value.

EXAMPLES**I - CLONING, EXPRESSION AND SEQUENCING OF H. FELIS UREASE GENE :****EXPERIMENTAL PROCEDURES FOR PART I :****Bacterial strains and culture conditions :**

H. felis (ATCC 49179) was grown on blood agar base no. 2 (Oxoid) supplemented with 5 % (v/v) lysed horse blood (BioMerieux) and an antibiotic supplement consisting of 10 ng ml⁻¹ vancomycin (Lederle Laboratories), 2.5 µg ml⁻¹ polymyxin B (Pfizer), 5µg ml⁻¹ trimethoprim (Sigma Chemical Co.) and 2.5 µg ml⁻¹ amphotericin B (E.R Squibb and Sons, Inc.). Bacteria were cultured on freshly prepared agar plates and incubated, lid uppermost, under microaerobic conditions at 37°C for 2-3 days. E. coli strains HB101 (Boyer and Roulland-Dussoix, 1969) and MC1061 (Maniatis et al., 1983), used in the cloning experiments, were grown routinely in Luria broth without glucose added or on Luria agar medium, at 37°C. Bacteria grown under nitrogen-limiting

conditions were passaged on a nitrogen-limiting solid medium consisting of ammonium-free M9 minimal medium (pH 7.4) supplemented with 0.4 % (w/v) D-glucose and 10 mM L-arginine (Cussac et al., 1992).

DNA manipulations :

All standard DNA manipulations and analyses, unless mentioned otherwise, were performed according to the procedures described by Maniatis et al. (1983).

Isolation of *H. felis* DNA :

Total genomic DNA was extracted by an sarkosyl-proteinase K lysis procedure (Labigne-Roussel et al., 1988). Twelve blood agar plates inoculated with *H. felis* were incubated in an anaerobic jar (BBL) with an anaerobic gaspak (BBL 70304) without catalyst, for 1-2 days at 37°C. The plates were harvested in 50 ml of a 15 % (v/v) glycerol - 9 % (w/v) sucrose solution and centrifuged at 5,000 rpm (in a Sorvall centrifuge), for 30 min at 4°C. The pellet was resuspended in 0.2 ml 50 mM D-glucose in 25 mM Tris-10 mM EDTA (pH 8.0) containing 5 mg ml⁻¹ lysozyme and transferred to a VTi65 polyallomer quick seal tube. A 0.2 ml aliquot of 20 mg ml⁻¹ proteinase K and 0.02 ml of 5M sodium perchlorate were added to the suspension. Cells were lysed by adding 0.65 ml of 0.5M EDTA -10 % (w/v) Sarkosyl, and incubated at 65°C until the suspension cleared (approximately 5 min). The volume of the tube was completed with a CsCl solution consisting (per 100 ml) of 126 g CsCl, 1 ml aprotinine, 99 ml TES buffer (30 mM Tris, 5 mM EDTA, 50 mM NaCl (pH 7.5)). Lysates were centrifuged at 45 000 rpm, for 15-18 h at 18°C. Total DNA was collected and dialysed against TE buffer (10 mM Tris, 1 mM EDTA), at 4°C.

Cosmid cloning :

Chromosomal DNA from H. felis was cloned into cosmid vector pILL575, as previously described (Labigne et al, 1991). Briefly, DNA fragments arising from a partial digestion with Sau3A were sized on a (10 to 40 %) sucrose density gradient and then ligated into a BamHI-digested and dephosphorylated pILL575 DNA preparation. Cosmids were packaged into phage lambda particles (Amersham, In Vitro packaging kit) and used to infect E. coli HB101. To screen for urease expression, kanamycin-resistant transductants were replica-plated onto solid nitrogen-mimicking medium (see above) containing (20 µg ml⁻¹) kanamycin that had been dispensed into individual wells of microtitre plates (Becton Dickinson). The microtitre plates were incubated aerobically, at 37°C for 2 days before adding 0.1 ml urease reagent (Hazell et al., 1987) to each of the wells. Ureolysis was detected within 5-6 h at 37°C by a colour change in the reagent. Several urease-positive cosmid clones were restriction mapped and one was selected for subcloning.

Subcloning of H. felis DNA :

A large-scale CsCl plasmid preparation of cosmid DNA was partially digested Sau3A. DNA fragments (7 - 11 kb) were electroeluted from an agarose gel and purified using phenol-chloroform extractions. Following precipitation in cold ethanol, the fragments were ligated into Bg/III-digested plasmid pILL570 (Labigne et al., 1991) and the recombinant plasmids used to transform competent E. coli MC1061 cells. Spectinomycin-resistant transformants were selected and screened for urease expression under nitrogen-rich (Luria agar) and nitrogen-limiting conditions.

Quantitative urease activity :

Cultures grown aerobically for 2.5 days at 37°C were harvested and washed twice in 0.85 % (w/v) NaCl. Pellets were resuspended in PEB buffer (0.1 M sodium phosphate buffer (pH 7.4) containing 0.01 M EDTA) and then sonicated by four 30-sec bursts using a Branson Sonifier model 450 set at 30 W, 50 % cycle. Cell debris was removed from the sonicates by centrifugation. Urease activities of the sonicates were measured in a 0.05 M urea solution prepared in PEB by a modification of the Berthelot reaction (Cussac et al., 1992). Urease activity was expressed as $\mu\text{mol urea min}^{-1}\text{mg}^{-1}$ bacterial protein.

Protein determination :

Protein concentrations were estimated with a commercial version of the Bradford assay (Sigma Chemicals).

Transposon mutagenesis :

Random insertional mutations were generated within cloned H. felis via a MiniTn3-Km delivery system (Labigne et al., 1992). In brief, E. coli HB101 cells containing the transposase-encoding plasmid pTCA were transformed with plasmid pILL570 containing cloned H. felis DNA. Transposition of the MiniTn3-Km element into the pILL570 derivative plasmids was effected via conjugation. The resulting cointegrates were then selected for resolved structures in the presence of high concentrations of kanamycin (500 mg l^{-1}) and spectinomycin (300 mg l^{-1}).

SDS-PAGE and Western blotting :

Solubilised cell extracts were analysed on slab gels, comprising a 4.5 % acrylamide stacking gel and 12.5 % resolving gel, according to the procedure of

Laemmli (Laemmli, 1970). Electrophoresis was performed at 200V on a mini-slab gel apparatus (Bio-Rad).

Proteins were transferred to nitrocellulose paper (Towbin et al., 1979) in a Mini Trans-Blot transfer cell (Bio-Rad) set at 100 V for 1 h (with cooling). Nitrocellulose membranes were blocked with 5 % (w/v) purified casein (BDH) in phosphate-buffered saline (PBS, pH 7.4) at room temperature, for 2 h (Ferrero et al., 1992). Membranes were reacted at 4°C overnight with antisera diluted in 1 % (w/v) casein prepared in PBS. Immunoreactants were then detected using a biotinylated secondary antibody (Kirkegaard and Perry Lab.) in combination with avidin-peroxidase (KPL). A substrate solution composed of 0.3 % (w/v) 4-chloro-1-naphthol (Bio-rad) was used to visualise reaction products.

DNA Sequencing :

DNA fragments to be sequenced were cloned into M13mp18 and M13mp19 (Meissing and Vieira, 1982) bacteriophage vectors (Pharmacia). Competent E. coli JM101 cells were transfected with recombinant phage DNA and plated on media containing X-gal (5-bromo-4-chloro-3-indolyl- β -D-galactopyranoside) and isopropyl- β -D-thiogalactopyranoside. Plaques arising from bacteria infected with recombinant phage DNA were selected for the preparation of single-stranded DNA templates by polyethylene glycol treatment (Sanger et al., 1977). Single-stranded DNA sequenced according to the dideoxynucleotide chain termination method using a Sequenase kit (United States Biochemical Corp.).

Nucleotide sequence accession number :

The nucleotide accession number is X69080 (EMBL Data Library).

RESULTS OF PART I EXPERIMENTS :**Expression of urease activity by *H. felis* cosmid clones :**

Cloning of partially digested fragments (30 to 45 kb in size) of *H. felis* chromosomal DNA into the cosmid vector pILL575 resulted in the isolation of approximately 700 cosmid clones. The clones were subcultured on nitrogen-limiting medium in order to induce urease expression (Cussac et al., 1992). Six of these were identified as being urease-positive after 5-6 h incubation (as described in the Experimental procedures section). No other urease-positive cosmid clones were identified, even after a further overnight incubation. Restriction enzyme analysis of 3 clones harbouring the urease-encoding cosmids revealed a common 28 kd DNA fragment. A cosmid (designated pILL199) containing DNA regions at both extremities of the common fragment was selected for subcloning.

Identification of *H. felis* genes required for urease expression when cloned in *E. coli* cells :

To define the minimum DNA region necessary for urease expression in *E. coli* cells, the urease-encoding cosmid pILL199 was partially digested with Sau3A and the fragments were subcloned into plasmid pILL570. The transformants were subcultured on nitrogen-rich and nitrogen-limiting media and screened for an urease-positive phenotype. Five transformants expressed urease activity when grown under nitrogen-limiting conditions, whereas no activity was detected following growth on nitrogen-rich medium. Restriction mapping analyses indicated that the urease-encoding plasmids contained inserts of between 7 and 11 kb. The

plasmid designated pILL205 was chosen for further studies.

Random mutagenesis of cloned H. felis DNA was performed to investigate putative regions essential for urease expression in E. coli and to localise the region of cloned DNA that contained the structural urease genes. Random insertion mutants of the prototype plasmid pILL205 were thus generated using the MiniTn3-Km element (Labigne et al, 1992). The site of insertion was restriction mapped for each of the mutated copies of pILL205 and cells harbouring these plasmids were assessed qualitatively for urease activity (figure 1). A selection of E. coli HB101 cells harbouring the mutated derivatives of pILL205 (designated "a" to "i") were then used both for quantitative urease activity determinations, as well as for the detection of the putative urease subunits by Western blotting.

The urease activity of E. coli HB101 cells harbouring pILL205 was $1.2 \pm 0.5 \mu\text{mol urea min}^{-1}\text{mg}^{-1}$ bacterial protein (table 1), which is approximately a fifth that of the parent H. felis strain used for the cloning. Insertion of the transposon at sites "a", "c", "d", "f" and "g" resulted in a negative phenotype, whilst mutations at sites "b", "e", "h" and "i" had no significant effect on the urease activities of clones harbouring these mutated copies of pILL205 (table 1). Thus mutagenesis of pILL205 with the MiniTn3-Km element identified three domains as being required for H. felis urease gene expression in E. coli cells.

Localisation of the H. felis urease structural genes :

Western blot analysis of extracts of E. coli cells harbouring pILL205 indicated the presence of two

This Sheet Has Been Replaced

polypeptides of approximately 30 and 66 kDa which cross-reacted with polyclonal H. felis rabbit antiserum (Figure 2A). These proteins were not produced by bacteria carrying the vector (pILL570). Native H. felis urease has been reported to be composed of repeating monomeric subunits with calculated molecular weights of 30 and 69 kDa (Turbett et al, 1992). Thus the 30 and 66 kDa proteins were thought to correspond to the ure A and ure B gene products, respectively. Interestingly an extract of E. coli cells harbouring the recombinant plasmid pILL763 (Cussac et al, 1992) containing the Helicobacter pylori ure A and ure B genes, expressed two polypeptides with approximate molecular sizes of 30 and 62 kDa which cross-reacted with the anti-H. felis antisera (figure 2B).

Table 1. Mutagenesis of *E. coli* clones and effect on urease activity.

plasmids ^a	Urease activity ^b ($\mu\text{mol urea min}^{-1} \text{mg}^{-1} \text{protein}$)
pILL205	1.2 ± 0.46 ^c
pILL205 :: a	neg ^d
pILL205 :: b	0.74 ± 0.32
pILL205 :: c	neg
pILL205 :: d	neg
pILL205 :: e	0.54 ± 0.15
pILL205 :: f	neg
pILL205 :: g	neg
pILL205 :: h	1.05 ± 0.25
pILL205 :: i	0.93 ± 0.35

^a *E. coli* cells harboured pILL205 and its derivatives constructed by transposon mutagenesis. The letters correspond to the insertion sites of the MiniTn3-transposon on pILL205.

^b Activities of bacteria grown aerobically for 3 days at 37 °C on solid M9 minimal medium supplemented with 10 mM L-arginine. The values represent the means $\pm$ standard deviations calculated from three determinations.

^c Urease activity was approximately a fifth as large as that of *H. felis* wild-type strain (ATCC 49179) i.e. $5.7 \pm 0.1 \mu\text{mol urea min}^{-1} \text{mg}^{-1} \text{protein}$ (Ferrero and Lee, 1991).

^d No activity detected (limit of detection was $< 1 \text{ nmol urea min}^{-1} \text{mg}^{-1}$ of bacterial protein).

This Sheet Has Been Replaced

Clones harbouring the mutated derivatives of pILL205, in all but one case, expressed the ure A and ure B gene products (Figures 2A, B). Given that several of the mutants (i.e. mutants "c", "d", "f" and "g") synthesised the urease subunits yet did not produce an active enzyme, it is possible to speculate that accessory functions essential for urease activity may have been disrupted by transposon insertion. In contrast, the mutant designated pILL205::a did not produce the ure B product and was urease-negative. Thus the site of transposon insertion was presumed to be located in the ure B gene. Sequence analyses of the DNA region corresponding to insertion site "a" were undertaken to elucidate potential open reading frames encoding the structural polypeptides of H. felis urease.

Sequence analyses of H. felis structural urease genes :

Sequencing of a 2.4 kb region of H. felis DNA adjacent to transposon insertion site "a" resulted in the identification of two open reading frames (ORFs) designated ure A and ure B which are transcribed in the same direction (figure 3). The transposon was confirmed to be located at 240 bp upstream from the end of ure B. Both ORFs commenced with an ATG start codon and were preceded by a site similar to the E. coli consensus ribosome-binding sequence (Shine and Dalgarno, 1974). The intergenic space for the H. felis structural genes consisted of three codons which were in phase with the adjacent open-reading frames. This suggests that, as has already been observed to be the case for Helicobacter pylori (Labigne et al, 1991), a single mutation in the stop codon of the ure A gene

would theoretically result in a fused single polypeptide.

The H. felis ure A and ure B genes encode polypeptides with calculated molecular weights of 26 074 kA and 61 663 Da, respectively, which are highly homologous at the amino-acid sequence level to the ure A and ure B gene products of H. pylori. The levels of identity between the corresponding ure A and ure B gene products of the two Helicobacter spp. was calculated to be 73.5 % and 88.2 % respectively. From the amino-acid sequence information, the predicted molecular weights of the ure A and ure B polypeptides from H. felis and H. pylori (Labigne et al, 1991) are very similar. Nevertheless the ure B product of H. felis had a lower mobility than the corresponding gene product from Helicobacter pylori when subjected to SDS-polyacrylamide gel electrophoresis (figure 2B)

II - EXPRESSION OF RECOMBINANT UREASE SUBUNIT PROTEINS FROM H. PYLORI AND H. FELIS : ASSESSMENT OF THESE PROTEINS AS POTENTIAL MUCOSAL IMMUNOGENS IN A MOUSE MODEL :

The aims of the study were to develop recombinant antigens derived from the urease subunits of H. pylori and H. felis, and to assess the immunoprotective efficacies of these antigens in the H. felis/mouse model. Each of the structural genes encoding the respective urease subunits from H. pylori and H. felis was independently cloned and over-expressed in Escherichia coli. The resulting recombinant urease antigens (which were fused to a 42 kDa maltose-binding protein of E. coli) were purified in large quantities from E. coli cultures and were immunogenic, yet enzymatically inactive. The findings demonstrated the

feasibility of developing a recombinant vaccine against H. pylori infection.

EXPERIMENTAL PROCEDURES FOR PART II :

Bacterial strains, plasmids and growth conditions :

H. felis (ATCC 49179) was grown on a blood agar medium containing blood agar base no. 2 (Oxoid) supplemented with 10% lysed horse blood (BioMérieux) and an antibiotic supplement consisting of vancomycin (10 µg/mL), polymyxin B (25 ng/mL), trimethoprim (5 µg/mL) and amphotericin B (2.5 µg/mL). Bacteria were cultured under microaerobic conditions at 37° C for 2 days, as described previously. E. coli strains MC1061 and JM101, used in cloning and expression experiments, were grown routinely at 37° C in Luria medium, with or without agar added. The antibiotics carbenicillin (100 µg/mL) and spectinomycin (100 µg/mL) were added as required.

DNA manipulations and analysis :

All DNA manipulations and analyses, unless mentioned otherwise, were performed according to standard procedures. Restriction and modification enzymes were purchased from Amersham (France). DNA fragments to be cloned were electroeluted from agarose gels and then purified by passage on Elutip mini-columns (Schleicher and Schull, Germany). Single-stranded DNA sequencing was performed using M13mp18 and M13mp19 bacteriophage vectors (Pharmacia, France). Single-stranded DNA templates were prepared from recombinant phage DNA by polyethylene glycol treatment. Sequencing of the templates was achieved according to the dideoxynucleotide chain termination

method using a Sequenase kit (United States Biochemical Corp., U.S.A.).

Preparation of inserts for cloning using the polymerase chain reaction (PCR) :

To clone the ureA genes of H. pylori and H. felis, degenerated 36-mer primers were conceived from the published urease sequences (Labigne et al., 1991 ; Ferrero and Labigne, 1993) (primer set #1 ; refer to table 2). Purified DNA from E. coli clones harbouring plasmids pILL763 and pILL207 (table 3), that encoded the structural genes of H. pylori and H. felis ureases, were used as template material in PCR reactions. Reaction samples contained : 10 - 50 ng of denatured DNA ; PCR buffer (50 mmol/L KCl in 10 mmol/L Tris-HCl [pH 8.3]) ; dATP, dGTP, dCTP and dTTP (each at a final concentration of 1.25 mmol/L) ; 2.5 mmol/L MgCl₂ ; 25 pmol of each primer and 0.5 μ L Tag polymerase. The samples were subjected to 30 cycles of the following programme : 2 min at 94° C, 1 min at 40° C.

The amplification products were cloned into the cohesive ends of the pAMP vector (figure 1) according to the protocol described by the manufacturer ("CloneAmp System", Gibco BRL ; Cergy Pontoise, France). Briefly, 60 ng of amplification product was directly mixed in a buffer (consisting of 50 mmol/L KCl, 1.5 mmol/L MgCl₂, 0.1 % (wt/vol) gelatine in 10 mmol/L Tris-HCl, pH 8.3) with 50 ng of the pAMP 1 vector DNA and 1 unit of uracil DNA glycosylase. Ligation was performed for 30 min at 37° C. Competent cells (200 μ L) of E. coli MC1061 were transformed with 20 μ L of the ligation mixture. Inserts were subsequently excised from the polylinker of the pAMP vector by double digestion with BamH1 and Pst1, and

then subcloned into the expression vector pMAL (New England Biolabs Inc., Beverly, USA) chosen for the production of recombinant antigens (pILL919 and pILL920, respectively, figure 13), as well as in M13mp bacteriophage for sequencing.

Amplification of a product containing the ureB gene of H. pylori was obtained by PCR using a couple of 35-mer primers (set #2, table 2). The PCR reaction mixtures were first denatured for 3 min at 94° C, then subjected to 30 cycles of the following programme : 1 min at 94° C, 1 min at 55° C and 2 min at 72° C. The purified amplification product (1850 bp was digested with EcoRI and PstI and then cloned into pMAL (pILL927, figure 2). Competent cells of E. coli MC1061 were transformed with the ligation reaction.

H. felis ureB was cloned in a two-step procedure, that allowed the production of both complete and truncated versions of the UreB subunit. Plasmid pILL213 (table 3) was digested with the enzymes DraI, corresponding to amino acid residue number 219 of the UreB subunit and HindIII. The resulting 1350 bp fragment was purified and cloned into pMAL that had been digested with XmnI and HindIII (pILL219, figure 2). In order to produce a clone capable of synthesizing a complete UreB protein, PCR primers were developed (set #3, table 2) that amplified a 685 bp fragment from the N-terminal portion of the ureB gene (excluding the ATG codon), that also overlapped the beginning of the insert in plasmid pILL219. The PCR amplified material was purified and digested with bamHI and HindIII, and then cloned into pMAL (pILL221, figure 14). A 1350 bp PstI-PstI fragment encoding the remaining portion of the UreB gene product was subsequently excised from pILL219 and cloned into a

linearised preparation of pILL221 (pILL222, figure 14).

Expression of recombinant urease polypeptides in the vector pMAL :

The expression vector pMAL is under the control of an inducible promoter (P_{lac}) and contains an open-reading frame (ORF) that encodes the production of MalE (Maltose-binding protein, MBP). Sequences cloned in-phase with the latter ORF resulted in the synthesis of MBP-fused proteins which were easily purified on amylose resin. Of the two versions of pMAL that are commercially available, the version not encoding a signal sequence (ie. pMAL-c2) synthesized greater amounts of recombinant proteins and was thus used throughout.

E. coli clones harbouring recombinant plasmids were screened for the production of fusion proteins, prior to performing large-scale purification experiments.

Purification of recombinant urease polypeptides :

Fresh 500 mL volumes of Luria broth, containing carbenicillin (100 μ g/mL and 2% (wt/vol) glucose, were inoculated with overnight cultures (5 mL) of E. coli clones. The cultures were incubated at 37° C and shaken at 250 rpm, until the $A_{600} = 0.5$. Prior to adding 1 mmol/L (final concentration) isopropyl- β -D-thiogalactopyranoside (IPTG) to cultures, a 1.0 mL sample was taken (non-induced cells). Cultures were incubated for a further 4 h at which time another 1.0 mL sample (induced cells) was taken. The non-induced and induced cell samples were later analysed by SDS-PAGE.

IPTG-induced cultures were centrifuged at 7000 rpm for 20 min, at 4° C and the supernatant discarded. Pellets were resuspended in 50 mL column buffer (200 mmol/L NaCl, 1 mmol/L EDTA in 10 mmol/L TrisHCl, pH 7.4), containing the following protease inhibitors (supplied by Boehringer, Mannheim, Germany) : 2 µmol/L leupeptin, 2 µmol/L pepstatin and 1 mmol/L phenylmethylsulphonyl fluoride (PMSF). Intact cells were lysed by passage through a French Pressure cell (16 000 lb/in²). Cell debris was removed by centrifugation and lysates were diluted in column buffer to give a final concentration of 2.5 mg protein/mL, prior to chromatography on a 2.6 cm x 20 cm column of amylose resin (New England Biolabs). The resin was washed with column buffer at 0.5 mL/min until the A₂₈₀ returned levels. The MBP-fused recombinant proteins were eluted from the column by washing with column buffer containing 10 mmol/L l-maltose.

Fractions containing the recombinant proteins were pooled and then dialysed several times at 4° C against a low salt buffer (containing 25 mmol/L NaCl in 20 mmol/L TrisHCl, pH 8.0). The pooled fractions were then loaded at a flow rate of 0.5 mL/min onto a 1.6 x 10 cm anion exchange column (HP-Sepharose , Pharmacia, Sweden) connected to a Hi-Load chromatography system (Pharmacia). Proteins were eluted from the column using a salt gradient (25 mmol/L to 500 mmol/L NaCl). Fractions giving high absorbance readings at A₂₈₀ were exhaustively dialysed against distilled water at 4° C and analysed by SDS-PAGE.

Rabbit antisera :

This Sheet Has Been Replaced

Polyclonal rabbit antisera was prepared against total cell extracts of H. pylori strain 85P (Labigne et al., 1991) and H. felis (ATCC49179). Polyclonal rabbit antisera against recombinant protein preparations of H. pylori and H. felis urease subunits was produced by immunizing rabbits with 100 µg of purified recombinant protein in Freund's complete adjuvant (Sigma). Four weeks later, rabbits were booster-immunized with 100 µg protein in Freund's incomplete adjuvant. On week 6, the animals were terminally bled and the sera kept at -20° C.

Protein analyzes by SDS-PAGE and western blotting :

Solubilized cell extracts were analyzed on slab gels, comprising a 4.5% acrylamide stacking gel and a 10% resolving gel, according to the procedure of Laemmli. Electrophoresis was performed at 200 V on a mini-slab gel apparatus (Bio-Rad, USA).

Proteins were transferred to nitrocellulose paper in a Mini Trans-Blot transfer cell (Bio-Rad) set at 100 V for 1 h, with cooling. Nitrocellulose membranes were blocked with 5% (wt/vol) casein (BDH, England) in phosphate-buffered saline (PBS, pH 7.4) with gentle shaking at room temperature, for 2 h. Membranes were reacted at 4° C overnight with antisera diluted in 1% casein prepared in PBS. Immunoreactants were detected using specific biotinylated secondary antibodies and streptavidin-peroxidase conjugate (Kirkegaard and Parry Lab., Gaithersburg, USA). Reaction products were visualized on autoradiographic film (Hyperfilm, Amersham, France) using a chemiluminescence technique (ECL system, Amersham).

Protein concentrations were determined by the Bradford assay (Sigma Chemicals corp., St Louis, USA).

This Sheet Has Been Replaced

Animal experimentation :

Six week old female Swiss Specific Pathogen-Free (SPF) mice were obtained (Centre d'Elevage R. Janvier, Le-Genest-St-Isle, France) and maintained on a commercial pellet diet with water ad libitum. The intestines of the animals were screened for the absence of Helicobacter muridarum. For all orogastric administrations, 100 μ L aliquots were delivered to mice using 1.0 mL disposable syringes, to which polyethylene catheters (Biotrol, Paris, France) were attached.

Preparation of sonicated extracts and inocula from H. felis cultures :

H. felis bacteria were harvested in PBS and centrifuged at 5000 rpm, for 10 min in a Sorvall RC-5 centrifuge (Sorvall, USA) at 4° C. The pellets were washed twice and resuspended in PBS. Bacterial suspensions were sonicated as previously described and were subjected to at least one freeze-thaw cycle. Protein determinations were carried out on the sonicates.

To ensure a virulent culture of H. felis for protection studies, H. felis bacteria were maintained in vivo until required. Briefly, mice were inoculated three times (with 10^{10} bacteria/mL), over a period of 5 days. The bacteria were reisolated from stomach biopsies on blood agar medium (4 - 7 days' incubation in a microaerobic atmosphere at 37° C). Bacteria grown for two days on blood agar plates were harvested directly in peptone water (Difco, USA). Bacterial viability and motility was assessed by phase microscopy prior to administration to animals.

Mouse protection studies :

Fifty μg of recombinant antigen and 10 μg cholera holotoxin (Sigma Chemical Corp.), both resuspended in HCO_3 , were administered orogastrically to mice on weeks 0, 1, 2 and 3. Mice immunized with sonicated H. felis extracts (containing 400 - 800 μg of total protein) were also given 10 μg of cholera toxin. On week 5, half of the mice from each group were challenged with an inoculum of virulent H. felis. The remainder of the mice received an additional "boost" immunization on week 15. On week 17 the latter were challenged with a culture of H. felis.

Assessment of H. felis colonisation of the mouse :

Two weeks after receiving the challenge dose (ie. weeks 7 and 19, respectively) mice were sacrificed by spinal dislocation. The Stomachs were washed twice in sterile 0.8% NaCl and a portion of the gastric antrum from each stomach was placed on the surfaces of 12 cm x 12 cm agar plates containing a urea indicator medium (2% urea, 120 mg Na_2HPO_4 , 80 mg KH_2PO_4 , 1.2 mg phenol red, 1.5 g agar prepared in 100 mL). The remainder of each stomach was placed in formal-saline and stored until processed for histology. Longitudinal sections (4 μm) of the stomachs were cut and routinely stained by the Giemsa technique. When necessary, sections were additionally stained by the Haematoxylin-Eosin and Warthin-Starry silver stain techniques;

The presence of H. felis bacteria in mouse gastric mucosa was assessed by the detection of urease activity (for up to 24 h) on the indicator medium, as well as by the screening of Giemsa-stained gastric sections that had been coded so as to eliminate observer bias. The numbers of bacteria in gastric sections were semi-quantitatively scored according to the following scheme : 0, no bacteria seen throughout

sections ; 1, few bacteria (< 20) seen throughout ; 2, occasional high power (H.P.) field with low numbers (< 20) of bacteria ; 3, occasional H.P. field with low to moderate numbers (< 50) of bacteria ; and 4, numerous (> 5) H.P. fields with high numbers of bacteria (> 50). Mononuclear cell infiltrates were scored as follows : 0, no significant infiltration ; 1, infiltration of low numbers of mononuclear cells limited to the submucosa and muscularis mucosa ; 2, infiltration of moderate numbers of mononuclear cells to the submucosa and muscularis mucosa, sometimes forming loose aggregates ; and 3, infiltration of large numbers of mononuclear cells and featuring nodular agglomerations of cells.

RESULTS OF PART II EXPERIMENTS :

Expression of Helicobacter urease polypeptides in E. coli :

Fragments containing the sequences encoding the respective UreA gene products of H. felis and H. pylori were amplified by PCR and cloned in-phase with an ORF encoding the 42 kDa MBP, present on the expression vector pMAL. Sequencing of the PCR products revealed minor nucleotidic changes that did not, however, alter the deduced amino acid sequences of the respective gene products. E. coli MC1061 cells transformed with these recombinant plasmids (pILL919 and pILL920, respectively) expressed fusion proteins with predicted molecular weights of approximately 68 kDa. Following chromatography on affinity (amylose resin) and anion exchange gel media (Q-Sepharose), these proteins were purified to high degrees of purity (figure 1). The yield from 2-L cultures of recombinant

E. coli cells was approximately 40 mg of purified antigen.

Similarly, the large UreB subunits of H. pylori and H. felis ureases were expressed in E. coli (plasmids pILL927 and pILL222, respectively) and produced fusion proteins with predicted molecular weights of 103 kDa. The yield in these cases was appreciably lower than for the UreA preparations (approximately 20 mg was recovered from 2-L of bacterial culture). Moreover, problems associated with the cleavage of the UreB polypeptides from the MBP portion of the fusion proteins were encountered. These difficulties were attributed to the large sizes of the recombinant UreB polypeptides.

Analysis of the recombinant urease polypeptides :

Western blot analyses of the antigen preparations with rabbit polyclonal antisera raised to whole-extracts of H. pylori and H. felis bacteria demonstrated that the antigens retained immunogenicity to the homologous as well as heterologous antisera (figures 14 and 15). The antisera did not recognize the MBP component alone. Cross-reactivity between the urease polypeptides of H. pylori and H. felis was consistent with the high degrees of identity between the amino acid sequences of these proteins.

Rabbit polyclonal antisera raised against purified recombinant UreA and UreB proteins prepared from H. pylori and H. felis strongly reacted with the urease polypeptides present in whole-cell extracts of the bacteria (figure 16). As we had already observed, the UreB subunit of H. felis urease migrated slightly higher on SDS-PAGE gels than did that of H. pylori (figure 16).

Preparation of *H. felis* inocula used in immunoprotection studies :

To ensure the virulence of *H. felis* bacterial inocula, bacteria were reisolated from *H. felis*-infected mouse stomachs (see Materials and methods). The bacteria were passaged a minimum number of times in vitro. Stock cultures prepared from these bacteria, and stored at -80° C, were used to prepare fresh inocula for other mouse protection studies. This procedure ensured that the inocula used in successive experiments were reproducible.

Immunization of mice against gastric *H. felis* infection :

Mice that had been immunized for three weeks with the given antigen preparations were divided into two lots and one half of these were challenged two weeks later with an *H. felis* inoculum containing 10⁷ bacteria/mL. One group of animals that had been immunized with recombinant *H. felis* UreA were also challenged but, unlike the other animals, were not sacrificed until week 19.

a) Protection at week 5 :

Eighty-five % of stomach biopsy samples from the control group of mice immunized with *H. felis* sonicate preparations were urease-negative and therefore appeared to have been protected from *H. felis* infection (table 4). This compared to 20% of those from the other control group of animals given MBP alone. The proportion of urease-negative stomachs for those groups of mice given the recombinant urease subunits varied from 70% (for *H. pylori* UreB) to 20% (for *H. pylori* UreA).

The levels of bacterial colonisation by H. felis was also assessed from coded histological slides prepared from gastric tissue. Due to the striking helical morphology of H. felis bacteria, the organisms could be readily seen on the mucosal surfaces of both gastric pit and glandular regions of the stomach. Histological evidence indicated that the levels of protection in mice was lower than that observed by the biopsy urease test : 25% and 20% of gastric tissue from mice immunized with H. felis sonicate preparations of H. pylori UreB, respectively, were free of H. felis bacteria.

Amongst certain groups of these mice the preponderance of urease-negative biopsies, as well as lower histological scores for bacterial colonisation (unpublished data), suggested that an immunoprotective response had been elicited in the animals. This response, however, may have been insufficient to protect against the inoculum administered during the challenge procedure.

b) Protection at week 17 :

The remaining mice, from each group of animals, were boosted on week 15. These mice were challenged at week 17 with an H. felis inoculum containing approximately 100-fold less bacteria than that used previously. Two weeks later all stomach biopsies from the MBP-immunized mice were urease-positive (table 4). In contrast, urease activity for gastric biopsies from mice immunized with the recombinant urease subunits varied from 50% for H. pylori UreA to 100% for H. felis UreB. The latter was comparable to the level of protection observed for the group of animals immunized with H. felis sonicated extracts. Histological evidence demonstrated that the UreB subunits of H.

felis and H. pylori protected 60% and 25% of immunized animals, respectively. This compared with a level of 85% protection for mice immunized with H. felis sonicated extracts. Immunization of mice with recombinant H. pylori UreA did not protect the animals. Similarly, the stomachs of all H. felis UreA-immunized mice, that had been challenged at week 5, were heavily colonised with H. felis bacteria at week 19 (table 4).

The urease gastric biopsy test, when compared to histological analysis of gastric tissue sections, gave sensitivity and specificity values of 63% and 95%, respectively. Thus histology proved to be the more accurate predictor of H. felis infection in the mouse.

Cellular immune response in immunized stomachs :

In addition to the histological assessment of H. felis colonisation, mouse gastric tissue was also scored (from 0 to 3) for the presence of a mononuclear cell response. In mice immunized with MBP alone, a mild chronic gastritis was seen with small numbers of mononuclear cells restricted to the muscularis mucosa and to the submucosa of the gastric epithelium. In contrast, there were considerable numbers of mononuclear cells present in the gastric mucosae from animals immunized with either the recombinant urease polypeptides, or with H. felis sonicate preparations. These inflammatory cells coalesced to form either loose aggregates, in the submucosal regions of the tissue, or nodular structures that extended into the mucosal regions of the gastric epithelia. The mononuclear cell response did not appear to be related to the presence of bacteria as the gastric mucosae from the H. felis UreA-immunized mice, that were

50

heavily colonized with H. felis bacteria, contained little or no mononuclear cells.

III- HELICOBACTER PYLORI hspA-B HEAT SHOCK GENE
CLUSTER : NUCLEOTIDE SEQUENCE, EXPRESSION AND
FUNCTION :

A homolog of the heat shock proteins (HSPs) of the GroEL class, reported to be closely associated with the urease of *Helicobacter pylori* (a nickel metalloenzyme), has recently been purified from *H. pylori* cells by Dunn et al, and Evans et al. (Infect. Immun. 60:1946, 1992, 1946 and 2125, respectively). Based on the reported N-terminal amino acid sequence of this immunodominant protein, degenerated oligonucleotides were synthesized in order to target the gene (hspB) encoding the GroEL-like protein in the chromosome of *H. pylori* strain 85P. Following gene amplification, a 108-base pair (bp)-fragment encoding the 36 first amino acids of the HspB protein was purified, and used a probe to identify in the *H. pylori* genomic bank a recombinant cosmid harboring the entire HspB encoding gene. The hspB gene was mapped to a 3.15 kilobases (kb) BglII restriction fragment of the pILL684 cosmid. The nucleotide sequence of that fragment subcloned into the pILL570 plasmid vector (pILL689) revealed the presence of two open reading frames (OFRs) designated hspA and hspB, the organization of which was very similar to be groESL bicistronic operons of other bacterial species. hspA and hspB encode polypeptides of 118 and 545 amino acids respectively, corresponding to calculated molecular masses of 13.0 and 58.2 kilodaltons (kDa), respectively. Amino acid sequence comparison studies revealed i) that the *H. pylori* HspA and HspB protein were highly similar to their bacterial homologs; ii) that the HspA *H. pylori* protein features a striking motif at the carboxyl terminus that other bacterial

GroEs-homologs lack ; this unique motif consists of a series of eight histidine residues resembling metal binding domain, such a nickel binding. Surprisingly, immediately upstream of the gene cluster an IS5 insertion element was found that was absent in the *H. pylori* genome, and was positively selectionned during the cosmid cloning process. The IS5 was found to be involved in the expression of the hspA and hspB genes in pILL689. The expression of the HspA and HspB proteins from the pILL689 plasmid was analyzed in minicell-producing strain. Both polypeptides were shown to be constitutively expressed in the *E. coli* cells. When the pILL689 recombinant plasmid was introduced together with the *H. pylori* urease gene cluster into an *E. coli* host strain, an increase of urease activity was observed suggesting a close interaction between the heat shock proteins and the urease enzyme. Supporting the concept of a specific function for the HspA chaperone, was the fact that whereas a single hspB copy was found in the *H. pylori* genome, two copies of the hspA were found in the genome, one linked to the hspB gene and one unlinked to the hspB gene. Attempts to construct isogenic mutants of *H. pylori* in the hspA and the hspB gene were unsuccessful suggesting that these genes are essential for the survival of the bacteria.

EXPERIMENTAL PROCEDURES FOR PART III :

Bacterial strains, plasmids, and culture conditions :

The cloning experiments were performed with genomic DNA prepared from *H. pylori* strain 85P. *H. pylori* strain N6 was used as the recipient strain for the electroporation experiments because of its favorable transformability. *E. coli* strain HB101 or

strain MC1061 were used as a host for cosmid cloning and subcloning experiments, respectively. *E. coli* P678-54 was used for preparation of minicells. Vectors and recombinant plasmids used in this study are listed in Table 1. *H. pylori* strains were grown on horse blood agar plates, supplemented with vancomycin (10 mg/l), polymyxin B (2,500 U/I), trimethoprim (5 mg/l), and amphotericin B (4 mg/l). Plates were incubated at 37°C under microaerobic conditions in an anaerobic jar with a carbon dioxide generator envelope (BBL 70304). *E. coli* strains were grown in L-broth without glucose (10 g of tryptone, 5 g of yeast extract, and 5 g of NaCl per liter ; pH 7.0) or on L-agar plates (1.5 % agar) at 37°C. For measurement of urease activity, the nitrogen-limiting medium used consisted of ammonium-free M9 minimal agar medium (pH7.4) containing 0.4 % D-glucose as the carbon source, and freshly prepared filter-sterilized L-arginine added to the final concentration of 10 mM. Antibiotic concentrations for the selection of recombinant clones were as follows (in milligrams per liter) : kanamycin, 20 ; spectinomycin, 100 ; carbenicillin, 100.

Preparation of DNA :

Genomic DNA from *H. pylori* was prepared as previously described. Cosmid and plasmid DNAs were prepared by an alkaline lysis procedure followed by purification in cesium chloride-ethidium bromide gradients as previously described.

Cosmid cloning :

The construction of the cosmid gene bank of *H. pylori* 85P in *E. coli* HB101, which was used for the cloning of the *H. pylori* hspA-B gene cluster, has been described previously.

DNA analysis and cloning methodology :

Restriction endonucleases, T4 DNA ligase, DNA polymerase I large (Klenow) fragment, and Taq polymerase were purchased from Amersham, T4 DNA polymerase from Biolabs, and calf intestinal phosphatase from Pharmacia. All enzymes were used according to the instructions of the manufacturers. DNA fragments were separated on agarose gels run in Tris-acetate buffer. The 1-kb ladder from Bethesda Research Laboratories was used as a fragment size standard. When necessary, DNA fragments were isolated by electroelution from agarose gels as previously described and recovered from the migration buffer by means of an Elutip-d minicolumn (Schleicher and Schuell, Dassel, Germany). Basic DNA manipulations were performed according to the protocols described by Sambrook et al.

Hybridization :

Colony blots for screening of the *H. pylori* cosmid bank and for identification of subclones were prepared on nitrocellulose membranes (Schleicher and Schuell, Dassel, Germany) according to the protocol of Sambrook et al. (43). Radioactive labelling of PCR-products was performed by random priming, using as primers the random hexamers from Pharmacia. Colony hybridizations were performed under high stringency conditions (5 x SSC, 0.1 % SDS, 50 % formamide, 42° C) (1 x SSC ; 150 mM NaCl, 15 mM sodium citrate, pH 7.0). For Southern blot hybridizations, DNA fragments were transferred from agarose gels to nitrocellulose sheets (0.45- μ m pore size ; Schleicher & Schuell, Inc.), and hybridized under low stringency conditions (5 x SSC, 0.1 % SDS, 30 or 40 % formamide, at 42° C with ³²p-labeled deoxyribonucleotide probes Hybridization was

revealed by autoradiography using Amersham Hyperfilm-MP.

DNA sequencing :

Appropriate fragments of plasmid DNA were subcloned into M13 mp 18/19 vectors. Single stranded DNA was prepared by phage infection of E. coli strain JM101. Sequencing was performed by the dideoxynucleotide chain termination method using the United States Biochemicals Sequenase kit. Both the M13 universal primer and additional specific primers (Fig.1) were used to sequence both the coding and non-coding DNA strands. Sequencing of double-stranded DNA was performed as previously described. Direct sequencing of PCR product was carried out following purification of the amplified, electroeluted PCR product through an Elutip-d minicolumn (Schleicher & Schuell) ; The classical protocol for sequencing using the Sequenase kit was then used with the following modifications : PCR product was denatured by boiling annealing mixture containing 200 picomoles of the oligonucleotide used as primer and DMSO to the final concentration of 1 % for 3 minutes ; the mixture was then immediately cool on ice ; the labeling step was performed in presence of manganese ions (mM).

Electroporation of H. pylori :

In the attempt to construct H. pylori mutants, appropriate plasmid constructions carrying the targeted gene disrupted by a cassette containing a kanamycin resistance gene (aph3'-III), were transformed into H. pylori strain N6 by means of electroporation as previously described. Plasmid pSUS10 harboring the kanamycin disrupted flaA gene was used as positive control of electroporation. After

electroporation, bacteria were grown on non-selective plates for a period of 48 h in order to allow for the expression of the antibiotic resistance and then transferred onto kanamycin-containing plates. The selective plates were incubated for up to 6 days.

Polymerase chain reaction (PCR) :

PCRs were carried out using a Perkin-Elmer Cetus thermal cycler using the GeneAmp kit (Perkin-Elmer Cetus). Classical amplification reaction involved 50 picomoles (pmoles) of each primer and at least 5 pmoles of the target DNA. The target DNA was heat denatured prior addition to the amplification reaction. Reaction consisted of 25 cycles of the following three steps : denaturation (94° C for 1 minute), annealing (at temperatures ranging between 42 and 55° C, depending on the calculated melting temperatures of the primers, for 2 min), and extension (72° C for 2 min). When degenerated oligonucleotides were used in non stringent conditions, up to 1000 pmoles of each oligonucleotide were added, 50 cycles were carried out, and annealing was performed at 42° C.

Analysis of proteins expressed in minicells :

Minicells harboring the appropriate hybrid plasmid were isolated and labeled with [³⁵S] methionine (50 µ Ci/ml). Approximately 100,000 cpm of acetone-precipitable material was subjected to sodium dodecyl sulfate (SDS) -polyacrylamide gel electrophoresis in a 12.5 % gel. Standard proteins with molecular weights ranging from 94,000 to 14,000 (low molecular-weights kit from Bio-Rad Laboratories) were run in parallel. The gel was stained and examined by fluorography, using En³Hance (New England Nuclear).

Urease activity :

Urease activity was quantitated by the Berthelot reaction by using a modification of the procedure which has already been described. Urease activity was expressed as micromoles of urea hydrolyzed per minute per milligram of bacterial protein.

RESULTS OF PART III EXPERIMENTS :Identification of a recombinant cosmid harboring the Helicobacter pylori GroEL-like heat shock protein encoding gene :

Based on the published N-terminal amino sequence of the purified heat shock protein of *H. pylori*, two degenerated oligonucleotides were synthesized to target the gene of interest in the chromosome of *H. pylori* strain 85P. The first one 5' - G C N A A R G A R A T H A A R T T Y T C N G - 3' where N stands for the four nucleotides, R = A and G, Y = T and C, H = T, C, and A, is derived from for the first 8 amino acids of the protein (AKEIKFSD) ; the second one 5' - C R T T N C K N C C N C K N G G N C C C A T - 3', where K = G and T, corresponds to the complementary codons specifying the amino acid from position 29 to position 36 (MGPRGRNV, ref). The expected size for the PCR product was 108 base pairs (bp). The amplification reaction was performed under low stringency conditions as described in the "Materials and Methods" section, and led to the synthesis of six fragments with size ranging from 400 bp to 100 bp. The three smallest fragments were electroeluted from an acrylamide gel, and purified. Direct sequencing of the PCR products permitted the identification of a DNA fragment encoding an amino acid sequence corresponding to the published sequence. This fragment was therefore

labeled and used as probe in colony hybridization to identify recombinant cosmids exhibiting homology to a 5' segment of the *H. pylori* GroEL-like encoding gene ; this gene was further designated hspB. The gene bank consists of 400 independent kanamycin-resistant *E. coli* transductants harboring recombinant cosmids. Of those one single clone hybridized with the probe, and harbored a recombinant plasmid designated pILL684, 46 kb in size. The low frequency observed when detecting the hspB gene (1 of 400) was unusual when compared with that of several cloned genes which were consistently detected in five to seven recombinant cosmids. In order to identify the hspB gene, fragments with sizes of 3 to 4 kb were generated by partial restriction of the pILL684 cosmid DNA with endonuclease Sau3A, purified, and ligated into the BglII site of plasmid vector pILL570. Of 100 subclones, x were positive clones, and one was further studied (pILL689) ; it contains a 3.15 kb insert, flanked by two BglII restriction sites, that was mapped in detail (Fig. 5). Using the PCR ³²P labeled probe, the 5' end of the hspB gene was found to map to the 632 bp HindIII-SphI central restriction fragment of pILL689, indicating that one could expect the presence of the entire hspB gene in the pILL689 recombinant plasmid.

DNA sequence and deduced amino acid sequence of the *H. pylori* hspA-B gene cluster :

The 3200 bp of pILL689 depicted in Fig. 5 were sequenced by cloning into M13mp18 and M13mp19, the asymmetric restriction fragments BglII-SphI, SphI-HindIII, HindIII-BglII ; each cloned fragment was independently sequenced on both strands 16 oligonucleotide primers (Fig.1) were synthesized to

confirm the reading and/or to generate sequences overlapping the independently sequenced fragments ; these were used as primers in double-stranded-DNA sequencing analyses.

The analysis of the sequence revealed two distinct genetic elements. First the presence of two open reading frames (ORFs), depicted in figure 5, transcribed in the same direction, that were designated hspA and hspB ; The nucleotide sequence and the deduced amino acid sequence of the two ORFs are presented in Fig. 6. The first codon of hspA begins 323 bp upstream of the leftward HindIII site of pILL689 (Fig. 5) and is preceded by a Shine-Dalgarno ribosome-binding site (RBS) (GGAGAA). The hspA ORF codes for a polypeptide of 118 amino acids. The initiation codon for the hspB ORF begins 25 nucleotides downstream the hspA stop codon ; it is preceded by a RBS site (AAGGA). The hspB ORF encodes a polypeptide of 545 amino acids and is terminated by a TAA codon followed by a palindromic sequence resembling a rho-independent transcription terminator (free energy, $\Delta G = -19.8$ kcal/mol) (Fig. 6). The N-terminal amino acid sequence of the deduced protein HspB was identical to the N-terminal sequence of the purified *H. pylori* heat shock protein previously published with the exception of the N-terminal methionine, which is absent from the purified protein and might be posttranslationally removed, resulting in a mature protein of 544 amino acids.

The deduced amino acid sequences of *H. pylori* HspA and HspB were compared to several amino acid sequences of HSPs of the GroES and GroEL class (Fig. 7). HspB exhibited high homology at the amino acid level with the *Legionella pneumophila* HtpB protein (82.9 % of similarities), with the *Escherichia coli*

GroEL protein (81.0 % of similarities), with the *Chlamydia psittaci* or *C. trachomatis* HspB protein (79.4 % of similarities), with *Clostridium perfringens* Hsp60 protein (80.7 % of similarities), and to a lesser extent to the GroEL-like proteins of *Mycobacterium*. However, like almost all the GroEL homologs, *H. pylori* HspB demonstrated the conserved carboxyl-terminus glycine-methionine motif (MGGMGGMGGMGGMM) which was recently shown to be dispensable in the *E. coli* GroEL chaperonin. The degree of homology at the amino acid level between the *H. pylori* HspA protein and the other GroES-like proteins is shown in Fig. 7. The alignment shown features a striking motif at the carboxyl terminus of the *H. pylori* HspA protein that other bacterial GroES-homologs lack. This unique highly charged motif consists of 27 additional amino acids capable of forming a loop between two double cysteine residues ; of the 27 amino acids, 8 are histidine residues highly reminiscent of a metal binding domain.

The second genetic element revealed by the sequence analysis, was the presence of an insertion sequence (IS5) 84 bp upstream of the hspA gene. The nucleotide sequence of this element matched perfectly that previously described for IS5 in *E. coli*, with the presence of a 16 nucleotide sequence (CTTGTTTCGCACCTTCC) that corresponds to one of the two inverted repeats which flank the IS5 element. Because of the perfect match at the DNA level, we suspected that the IS5 was not initially present in the *H. pylori* chromosome, but had rather inserted upstream of the hspA-HspB gene cluster during the cloning process, a hypothesis that needed to be confirmed by further analyses.

Identification of the upstream sequence of the hspA-B gene cluster in H. pylori chromosome :

The presence of the IS5 was examined by gene amplification using two oligonucleotides, one being internal to the IS5 element and the other one downstream of the IS5 element (oligo #1 and #2, Fig. 6), to target a putative sequence i) in the chromosome of H. pylori strain 85P, ii) in the initial cosmid pILL684, and iii) in the 100 subclones resulting of the Sau3A partial restriction of the pILL684 recombinant cosmid. IS5 was absent from the chromosome of H. pylori, and was present in the very first subcultures of the E. coli strain harboring cosmid pILL684. Among the 100 pILL684 subclone derivatives which appeared to contain all or part of the IS5 sequence, we then looked for a subclone harboring the left end side of the IS5 plus the original upstream sequence of the hspA-hspB gene cluster. This screening was made by restriction analysis of the different Sau3A partial generated subclones. The restriction map of one (pILL694) of the plasmids fulfilling these criteria is shown in Fig. 5. The left end side of the IS5 nucleotide sequence was determined ; the presence of a 4-bp duplication CTAA on both side of the 16-bp inverted repeats of the IS5 element (Fig. 6) allowed us to confirm the recent acquisition of the IS5 element by transposition. A 245-nucleotide sequence was then determined that mapped immediately upstream of the IS5 element (shown Fig. 6). This sequence consists of a non coding region in which the presence of a putative consensus heat shock promoter sequence was detected ; it shows a perfectly conserved -35 region (TAACTCGCTTGAA) and a less consentaneous -10 region (CTCAATTA). Two oligonucleotides (#3 and #4, shown on Fig.2) were synthesized which mapped to

sequences located on both side of the IS5 element present in the recombinant cosmid ; these two oligonucleotides should lead to the amplification of a XXXXbp fragment when the IS5 sequence is present and a fragment in the absence of the IS5. The results of the PCR reaction using as target DNA the pILL684 cosmid, the pILL694 plasmid, and the *H. pylori* 85P chromosome fit the predictions (results not shown). Moreover, direct sequencing of the PCR product obtained from the *H. pylori* chromosome was performed and confirmed the upstream hspA-hspB reconstructed sequence shown in Fig. 6 (B). To further confirm the genetic organization of the whole sequenced region, two probes were prepared by gene amplification of the pILL689 plasmid using oligonucleotides #5 and #6, and #7 and #8 (Fig. 6). ; they were used as probes in Southern hybridization experiments under low stringency conditions against an HindIII digest of the *H. pylori* 85P chromosome. The results demonstrate that no other detectable rearrangement had occurred during the cloning process (data not shown). These experiments allowed us to demonstrate that whereas a single copy of the hspB gene was present in the chromosome of *H. pylori* strain 85, two copies of the hspA gene were detected by Southern hybridization.

Analysis of polypeptides expressed in minicells :

The pILL689 and the pILL692 recombinant plasmids and the respective cloning vectors pILL570, and pACYC177, were introduced by transformation into *E. coli* P678-54, a minicell-producing strain. The pILL689 and pILL692 plasmids (Fig. 5) contain the same 3.15-kb insert cloned into the two vectors. pILL570 contains upstream of the poly-cloning site a stop of transcription and of translation ; the orientation of

the insert in pILL689, was made in such way that the transcriptinnal stop was located upstream of the IS5 fragment and therefore upstream of the hspA and HspB genes. Two polypeptides that migrated with polypeptides having apparent molecular weights of 60 kDa and 14 kDa were clearly detected in minicell-experiments from pILL689 and pILL692 (results not shown), whereas they were absent from the corresponding vectors ; these results indicated that the hspA and hspB genes were constitutively expressed from a promoter located within the IS5 were constitutively expressed from a promoter located within the IS5 element. Moreover, whereas the amount of polypeptides visualized on the SDS gel was in good agreement with the copy number of the respective vectors, the intensity of the two polypeptidic bands suggested a polycistronic transcription of the two genes.

Attempts to understand the role of the Hspa and HspB proteins :

Two disruptions of genes were achieved in E. coli by inserting the Km cassette previously described within the hspA or the hspB gene of plasmids pILL686 and pILL691. This was done in order to return the disrupted genes in *H. pylori* by electroporation, and to select for allelic replacement. The pILL696 resulting plasmid encoded a truncated form of the Hspa protein, corresponding to the deletion of the C-terminal end amino acid sequence ; in that plasmid the Km cassette was inserted in such way that the promoter of the Km gene could serve as promoter for the hspB downstream gene. The pILL687 and pILL688 plasmids resulted from the insertion of the Km cassette in either orientation within the hspB gene. None of these

constructs led to the isolation of kanamycin transformants of *H. pylori* strain N6, when purified pILL687, pILL688, pILL696 plasmids (Table 2, Fig. 5) were used in electroporation experiments, whereas the pSUS10 plasmid used as positive control always did. These results suggest the *H. pylori* HspA and HspB protein are essential proteins for the survival of *H. pylori*.

Because of i) the constant description in the literature of a close association of the HspB protein with the urease subunits ; -ii) the unique structure of the HspA protein with the C-terminal sequence reminiscent of a nickel binding domain, and iii) of the absence of viable hspA and/or hspB mutants of *H. pylori*, we attempted to demonstrate a role of the *H. pylori* Hsps proteins in relations with the *H. pylori* urease by functional complementation experiments in *E. coli*. Plasmids pILL763 or pILL753 (both pILL570 derivatives, Table 5) encoding the urease gene cluster were introduced with the compatible pILL692 plasmid (pACYC177 derivative) that constitutively expresses the HspA et HspB polypeptides as visualized in minicells. In both complementations, the expression of the HspA and HspB proteins in the same *E. coli* cell allows to observe a three fold increase in the urease activity following induction of the urease genes on minimum medium supplemented with 10 mM L- Arginine as limiting nitrogen source.

Table 5 : Vectors and hybrid plasmids used in this study.

Plasmid	Vector	Size (kb)	Characteristics (a)	Origin or Reference
	pII.L575	10	Mob, Cos, Km	-
	pII.L570	5.3	Mob, Sp	-
	pACYC177	3.9	Ap, Km	-
pII.L600	pBR322	5.7	Ap, Km, source of Km-cassette	-
pII.L684	pII.L575	46	Mob, Km, cosmid containing <i>H. pylori hspA-B</i>	<i>Sau3A</i> partial digest of <i>H. pylori</i> 85P DNA
pII.L685	pII.L570	9.29	Mob, Sp, plasmid containing <i>H. pylori hspB</i>	<i>Sau3A</i> partial digest of pII.L684
pII.L686	pUC19 ^c	4.5	Ap, plasmid containing <i>H. pylori hspB</i>	1.9-kb <i>HgIII</i> - <i>Clal</i> pII.L685 cloned into pUC19 ^a
	pUC19 ^(c)	5.9	Ap, Km, <i>H. pylori hspB</i> Ω Km-orientation A (b)	1.4-kb <i>SmaI</i> - <i>SmaI</i> pII.L600 cloned into pII.L686
pII.L688	pUC19 ^(c)	5.9	Ap, Km, <i>H. pylori hspB</i> Ω Km-orientation B (b)	1.4-kb <i>SmaI</i> - <i>SmaI</i> pII.L600 cloned into pII.L686
pII.L689	pII.L570	8.45	Mob, Sp, plasmid containing <i>H. pylori hspA-B</i>	<i>Sau3A</i> partial digest of pII.L684
pII.L691	pUC19 ^(c)	3.9	Ap, plasmid containing <i>H. pylori hspA</i> 1.3-kb	<i>SphI</i> - <i>SphI</i> pII.L689 cloned into pUC19 ^a
pII.L692	pACYC177	7.05	Ap, Km, plasmid containing <i>H. pylori hspA-B</i>	3.15-kb <i>BglIII</i> pII.L689 cloned into pACYC177
pII.L694	pII.L570	8.7	Sp, plasmid containing left end of IS5	<i>Sau3A</i> partial digest of pII.L684
pII.L696	pUC19 ^(c)	5.3	Ap, Km, <i>H. pylori hspA</i> Ω Km-orientation A (b)	1.4-kb <i>SmaI</i> - <i>SmaI</i> pII.L600 cloned into pII.L691
pSUS10	pIC20R2	7.7	Ap, Km, <i>H. pylori flaA</i> Ω Km	-
pII.L753	pII.L570	16.5	Sp, plasmid containing <i>ureA,B,C,D,E,F,G,H,I</i>	-
pII.L763	pII.L570	14.75	Sp, plasmid containing <i>ureA,B,E,F,G,H,I</i>	-

(a) Mob, conjugative plasmid due to the presence of OriT; Ap, Km, and Sp, resistance to ampicillin, kanamycin, and spectinomycin, respectively; Cos, presence of lambda cos site.

(b) Orientation A indicates that the Kanamycin promoter initiates transcription in the same orientation as that of the gene where the cassette has been inserted; orientation B, the opposite.

(c) pUC19^a and pUC19^b : derivatives from pUC19 vector in which the the *SphI* and *HindIII* site, respectively, have been end-filled by using the Klenow polymerase and self religated.

IV - EXPRESSION, PURIFICATION AND IMMUNOGENIC
PROPERTIES OF H. PYLORI HSPA AND HSPB :

EXPERIMENTAL PROCEDURE FOR PART IV :

Expression and purification of recombinant fusion proteins :

The MalE-HspA, and MalE-HspB fusion proteins were expressed following the cloning of the two genes within the pMAL-c2 vector as described in the "Results" section using the following primers :

oligo #1 ccggagaattcAAGTTTCAACCATTAGGAGAAAGGGTC

oligo #2 acgttctgcagTTTAGTGTTTTTTGTGATCATGACAGC

oligo #3 ccggagaattcGCAAAAGAAATCAAATTTTCAGATAGC

oligo #4 acgttctgcagATGATACCAAAAAGCAAGGGGGCTTAC

Two liters of Luria medium containing glucose (30%) and ampicillin (100 µg/ml) were inoculated with 20 ml of an overnight culture of strain MC1061 containing the fusion plasmid and incubated with shaking at 37°C. When the OD600 of the culture reached 0.5, IPTG (at a final concentration of 10 mM) was added, and the cells were incubated for a further 4 hours. Cells were harvested by centrifugation (5000 rpm for 30 min at 4°C), resuspended in 100 ml of column buffer consisting of 10 mM Tris-HCl, 200 mM NaCl, 1 mM EDTA supplemented with protease inhibitors [(Leupeptin (2µM) - Pepstatin (2µM) - PMSF (1mM) - Aprotinin (1:1000 dilution)], and passed through a French press. After centrifugation (10,000 rpm for 20 min at 4°C), the supernatant were recovered and diluted (2-fold) with column buffer. The lysate was filtered through a 0.2 µm nitrocellulose filter prior to loading onto a preequilibrated amylose resin (22 x 2.5 cm). The fusion proteins were eluted with a 10mM maltose solution prepared in column buffer, and the fractions

containing the fusion proteins were pooled, dialyzed against distilled water, and lyophilized. Fusion proteins were resuspended in distilled water at a final concentration of 2 mg of lyophilized material/ml, and stored at -20°C. Concentration and purity of the preparations were controlled by the Bradford protein assay (Sigma Chemicals) and SDS-PAGE analyses.

Nickel binding properties of recombinant proteins :

E. coli MC1061 cells, containing either the pMAL-c2 vector or derivative recombinant plasmids, were grown in 100 ml-Luria broth in the presence of carbenicillin (100 µg/ml). The expression of the genes was induced with IPTG for four hours. The cells were centrifuged and the pellet was resuspended in 2 ml of Buffer A (6M guanidine hydrochloride, 0.1 M NaH₂PO₄, 0.01MTris, pH8.0). After gentle stirring for one hour at room temperature, the suspensions were centrifuged at 10,000 g for 15 min at 4°C. A 1.6 ml aliquot of Nickel-Nitrilo-Tri-Acetic resin (Nickel-NTA, QIA express), previously equilibrated in Buffer A, was added to the supernatant and this mixture was stirred at room temperature for one hour prior to loading onto a column. The column was washed with 20 ml buffer A, then 30 ml buffer B (8M urea, 0.1M Na-phosphate, 0.01MTris-HCl, pH8.0). The proteins were eluted successively with the same buffer as buffer B adjusted to pH 6.3 (Buffer C), pH 5.9 (Buffer D) and pH 4.5 (Buffer E) and Buffer F (6M guanidine hydrochloride, 0.2M acetic acid). Fifty µl of each fraction were mixed with 50 µl of SDS buffer and loaded on SDS gels.

Human sera :

Serum samples were obtained from 40 individuals, 28 were H. pylori-infected patients as confirmed by a positive culture for H. pylori and histological examination of the biopsy, and 12 were uninfected patients. The sera were kindly provided by R. J. Adamek (University of Bochum, Germany).

Immunoblotting :

Upon completion of SDS-PAGE runs in a Mini-PROTEAN II electrophoresis cell, proteins were transferred to nitrocellulose paper in a Mini Trans-Blot transfer cell (Bio-Rad) set at 100 V for 1 h (with cooling). Immunostaining was performed as previously described (Ferrero et al., 1992), except that the ECL Western blotting detection system (Amersham) was used to visualize reaction products. Human sera and the rabbit antiserum, raised against a whole-cell extract of H. pylori strain 85P, were diluted 1:1000 and 1:5000, respectively, in 1% (w/v) casein prepared in phosphate-buffered saline (PBS, pH7.4).

Serological methods [enzyme-linked immunosorbent assay, (ELISA)] :

The following quantities of antigens were absorbed onto 96-well plates (Falcon 3072) : 2.5 µg of protein MalE, 5 µg of MalE-HspA, or 2.5 µg of MalE-HspB. The plates were left overnight at 4°C, then washed 3 times with ELISA wash solution (EWS) [1% PBS containing 0.05% (v/v) Tween 20]. Saturation was achieved by incubating the plates for 90 min at 37°C in EWS supplemented with 1% milk powder. Wells were again washed 3 times with EWS and then gently agitated for 90 min at 37°C in the presence of human sera (diluted 1:500 in EWS with 0.5% milk powder), under

agitation. Bound imunoglobulins were detected by incubation for 90 min at 37°C with biotinylated secondary antibody (goat anti-human IgG, IgA or IgM diluted [1:1000] in EWS supplemented with 0.5% milk powder) in combination with streptavidin-peroxidase (1:500) (Kirkegaard and Perry Lab.). Bound peroxidase was detected by reaction with the citrate substrate and hydrogen peroxide. Plates were incubated in the dark, at room temperature, and the optical density at 492 nm was read at intervals of 5, 15 and 30 min in an ELISA plate reader. After 30 min, the reaction was stopped by the addition of hydrochloric acid to a final concentration of 0.5M.

RESULTS OF PART IV EXPERIMENTS :

Construction of recombinant plasmids producing inducible Male-HspA, and HspB fusion proteins :

The oligonucleotides #1 and #2 (hspA) and #3 and #4 (hspB) were used to amplify by PCR the entire hspA and the hspB genes, respectively. The PCR products were electroeluted, purified and restricted with EcoRI and PstI. The restricted fragments (360 bp and 1600 bp in size, respectively) were then ligated into the EcoRI-PstI restricted pMAL-c2 vector to generate plasmids designated pILL933 and pILL934, respectively. Following induction with IPTG, and purification of the soluble protein on amylose columns, fusion proteins of the expected size (55 kDa for pILL933 [figure 17], and 100 kDa for pILL934) were visualized on SDS-PAGE gels. Each of these corresponded to the fusion of the Male protein (42.7 kDa) with the second amino-acid of each of the Hsp polypeptides. The yield of the expression of the fusion proteins was 100 mg for

MalE-HspA and 20 mg for MalE-HspB when prepared from 2 liters of broth culture.

Study of the antigenicity of the HspA and HspB fusion proteins, and of the immunogenicity of HspA and HspB in patients infected with *H. pylori* :

In order to determine whether the fusion proteins were still antigenic, each was analyzed by Western blot with rabbit antiserum raised against the MalE protein and a whole-cell extract of *H. pylori* strain 85P. Both fusion proteins were immunoreactive with antibody to MalE (not shown) and with the anti-*H. pylori* antiserum. The anti-*H. pylori* antiserum did not recognize the purified MalE protein (figure 18). These results demonstrated that the fusion proteins retained their antigenic properties ; in addition, whereas the HspB protein was known to be immunogenic, this is the first demonstration that HspA per se is immunogenic in rabbits.

In the same way, in order to determine whether the HspA and HspB polypeptides were immunogenic in humans, the humoral immune response against HspA and/or HspB in patients infected with *H. pylori* was analyzed and compared to that of uninfected persons using Western immunoblotting assays and enzyme-linked immunosorbent assays (ELISA). None of the 12 sera of the *H. pylori*-negative persons gave a positive immunoblot signal with MalE, MalE-HspA, or MalE-HspB proteins (figure 18). In contrast, of 28 sera from *H. pylori*-positive patients, 12 (42.8%) reacted with the HspA protein whilst 20 (71.4%) recognized the HspB protein. All of the sera that recognized HspA also reacted with the HspB protein. No association was observed between the immune response and the clinical presentation of the *H. pylori* infection although such

a conclusion might be premature because of the small number of strains analyzed.

Nickel binding properties of the fused MalE-HspA protein :

MBP-HspA recombinant protein expressed following induction with IPTG, was purified from a whole cell extract by one step purification on nickel affinity column whereas the MBP alone, nor MBP-HspB exhibited this property. Figure 18 illustrates the one step purification of the MBP-HspA protein that was eluted as a monomer at pH6.3, and as a monomer at pH4.5. The unique band seen in panel 7 and the two bands seen in panel 5 were both specifically recognized with anti-HspA rabbit sera. This suggested that the nickel binding property of the fused MBP-HspA protein might be attributed to the C-terminal sequence of HspA which is rich in Histidine and Cysteine residues.

SEQUENCE LISTING

(1) GENERAL INFORMATION:

(i) APPLICANT:

(A) NAME: INSTITUT PASTEUR
(B) STREET: 25-28 rue du Dr Roux
(C) CITY: PARIS CEDEX 15
(E) COUNTRY: FRANCE
(F) POSTAL CODE (ZIP): 75724
(G) TELEPHONE: 45.68.80.94
(H) TELEFAX: 40.61.30.17

(A) NAME: INSTITUT NATIONAL DE LA SANTE ET DE LA
RECHERCHE MEDICALE
(B) STREET: 101 rue de Tolbiac
(C) CITY: PARIS CEDEX 13
(E) COUNTRY: FRANCE
(F) POSTAL CODE (ZIP): 75654
(G) TELEPHONE: 44.23.60.00
(H) TELEFAX: 45.85.07.66

(ii) TITLE OF INVENTION: IMMUNOGENIC COMPOSITIONS AGAINST
HELICOBACTER INFECTION, POLYPEPTIDES FOR USE IN THE
COMPOSITIONS AND NUCLEIC ACID SEQUENCES ENCODING SAID
POLYPEPTIDES.

(iii) NUMBER OF SEQUENCES: 8

(iv) COMPUTER READABLE FORM:

(A) MEDIUM TYPE: Floppy disk
(B) COMPUTER: IBM PC compatible
(C) OPERATING SYSTEM: PC-DOS/MS-DOS
(D) SOFTWARE: PatentIn Release #1.0, Version #1.25 (EPO)

(v) CURRENT APPLICATION DATA:

APPLICATION NUMBER: EP 93401309.5

(2) INFORMATION FOR SEQ ID NO: 1:

(i) SEQUENCE CHARACTERISTICS:

(A) LENGTH: 2619 base pairs
(B) TYPE: nucleic acid
(C) STRANDEDNESS: single
(D) TOPOLOGY: linear

(ii) MOLECULE TYPE: DNA (genomic)

(ix) FEATURE:

(A) NAME/KEY: misc_feature

CLAIMS

1. Immunogenic composition, capable of inducing antibodies against Helicobacter infection, characterised in that it comprises :

i) at least one sub-unit of a urease structural polypeptide from Helicobacter pylori, or a fragment thereof, said fragment being recognised by antibodies reacting with Helicobacter felis urease, and/or at least one sub-unit of a urease structural polypeptide from Helicobacter felis, or a fragment thereof, said fragment being recognised by antibodies reacting with Helicobacter pylori urease ;

ii) and/or, a Heat Shock protein (HSP), or chaperonin, from Helicobacter, or a fragment of said protein.

2. Immunogenic composition according to claim 1 capable of inducing protective antibodies.

3. Immunogenic composition according to claim 1 characterised in that it includes component (i), which comprises or consists of the Helicobacter felis urease structural polypeptide(s) encoded by the ure A and/or ure B genes of plasmid pILL205 (CNCM I-1355), a polypeptide exhibiting at least 90 % homology with the said polypeptide(s), or a fragment thereof having at least 6 amino-acids and being recognised by antibodies reacting with Helicobacter pylori urease.

4. Immunogenic composition according to claim 1, characterised in that it includes component ii) which is a HSP from Helicobacter pylori, or a fragment thereof.

5. Immunogenic composition according to any of preceding claims characterised in that the HSP is HSP A and/or HSP B encoded by the hsp A and/or hsp B genes respectively, of plasmid pILL689 (CNCM I-1356), or a

This Sheet Has Been Replaced

polypeptide exhibiting at least 75 % homology with the said HSP's, or a fragment of either or both of these proteins having at least 6 amino-acids.

6. Pharmaceutical composition for use as a vaccine in protecting against Helicobacter infection, particularly against Helicobacter pylori and Helicobacter felis, characterised in that it comprises the immunogenic composition of any of claims 1-5, in combination with physiologically acceptable excipient(s) and possibly adjuvants.

7. Proteinaceous material characterised in that it comprises at least one of the Helicobacter felis polypeptides encoded by the urease gene cluster of the plasmid pILL205 (CNCM I-1355), including the structural and accessory urease polypeptides, or a polypeptide having at least 90 % homology with said polypeptides, or a fragment thereof.

8. Proteinaceous material according to claim 7, characterised in that it consists of or comprises the gene product of ure A and/or ure B as illustrated in figure 3, or a fragment having at least 6 amino-acids, or a variant of these gene products having at least 90 % homology, said fragment and said variant being recognised by antibodies reacting with Helicobacter pylori urease.

9. Proteinaceous material according to claim 7 characterised in that it consists of or comprises the gene product of ure I, as illustrated in figure 9, or a fragment thereof having at least 6 amino-acids, or a variant of the gene product having at least 75 % homology, said fragment and said variant having the capacity to activate the ure A and ure B gene products in the presence of the remaining urease "accessory" gene products.

10. Nucleic acid sequence characterised in that it comprises :

- (i) at least one sequence coding for the proteinaceous material of any one of claims 6-9 ;
- or (ii) a sequence complementary to sequence (i) ;
- or (iii) a sequence capable of hybridising to sequences (i) or (ii) under stringent conditions ;
- iv) a fragment of any of sequences (i), (ii) or (iii) comprising at least 10 consecutive nucleotides.

11. Nucleic acid sequence according to claim 9 characterised in that it comprises the sequence of plasmid pILL205 (CNCM I-1355), for example the sequence of Figure 3, in particular that coding for the gene product of ure A and for ure B or the sequence of Figure 9 (Ure I), or a sequence capable of hybridising to these sequences under stringent conditions, or a sequence complementary to these sequences, or a fragment comprising at least 10 consecutive nucleotides of these sequences.

12. Expression vector characterised in that it contains a nucleic acid sequence according to claim 10 or 11.

13. Plasmid pILL205 (CNCM I-1355).

14. Oligonucleotide suitable for use as a primer in a nucleic acid amplification reaction, characterised in that it comprises from 10 to 100 consecutive nucleotides of the sequence of claim 10 or 11.

15. Nucleotide probe characterised in that it comprises a sequence according to any one of claims 9 or 10, with an appropriate labelling means.

16. Prokaryotic or eukaryotic host cell stably transformed by an expression vector according to claim 12 or 13.

103

17. Proteinaceous material characterised in that it comprises at least one of the Heat Shock Proteins (HSP), or chaperonins, of Helicobacter pylori, or a fragment thereof.

18. Proteinaceous material according to claim 17, characterised in that it comprises or consists of HSP A and/or HSP B, having the amino-acid sequence illustrated in Figure 6, or a polypeptide having at least 75 %, and preferably at least 80 % homology with said polypeptide, or a fragment thereof, comprising at least 6 amino-acids.

19. Proteinaceous material according to claim 18 characterised in that it comprises or consists of the HSP A C-terminal sequence :

G S C C H T G N H D H K H A K E H E A C C H D H K K H
or a fragment comprising at least 6 consecutive amino-acids of this sequence.

20. Nucleic acid sequence characterised in that it comprises :

i) a sequence coding for the proteinaceous material of any one of claims 17 to 19 or of any one of the proteinaceous materials of claims 7 to 9 ;
or ii) a sequence complementary to sequence (i) ;
or iii) a sequence capable of hybridizing to sequence (i) or (ii) under stringent conditions ;
or iv) a fragment of any of sequences (i), (ii) or (iii) comprising at least 10 nucleotides.

21. Nucleic acid sequence according to claim 20 characterised in that it comprises all or part of the sequence of plasmid pILL689 (CNCM I-1356), for example the sequence of figure 6, in particular that coding for HSP A and/or HSP B, or a sequence complementary to this sequence, or a sequence capable of hybridizing to this sequence under stringent conditions, or a fragment thereof.

This Sheet Has Been Replaced

22. Expression vector characterised in that it contains a nucleic acid sequence according to claim 20 or 21.

23. Plasmid pILL689 (CNCM I-1356).

24. Oligonucleotide suitable for use as a primer in a nucleic acid amplification reaction, characterised in that it comprises from 10 to 100 consecutive nucleotides of the sequence of claim 20 or 21.

25. Nucleotide probe, characterised in that it comprises a sequence according to any one of claims 20 or 21 with an appropriate labelling means.

26. Microorganism, stably transformed by an expression vector according to claim 22 or 23.

27. Monoclonal or polyclonal antibodies or fragments thereof, to the proteinaceous material of any one of claims 8 to 10, characterised in that they are either specific for the Helicobacter felis material, or alternatively, cross-react with the gene products of the urease gene cluster of Helicobacter pylori.

28. Monoclonal or polyclonal antibodies according to claim 27 characterised in that they recognise both the Helicobacter felis ure A and/or ure B gene product, and the Helicobacter pylori ure A and/or ure B gene product.

29. Monoclonal or polyclonal antibodies or fragments thereof, to the proteinaceous material of claims 17 or 18, characterised in that they are either specific for the Helicobacter pylori material or, alternatively, cross-react with GroEL-like proteins or GroES-like proteins from bacteria other than Helicobacter.

30. Monoclonal or polyclonal antibodies according to claim 29 characterised in that they recognise specifically the HSP A C-terminal sequence.

31. Use of the immunogenic composition of claim 1 for the preparation of a vaccine suitable for use in man and animals against Helicobacter infection, particularly against Helicobacter pylori and Helicobacter felis.

32. Use of the antibodies of claims 27 to 30 in a therapeutic composition for treating infection by Helicobacter, in particular Helicobacter pylori, Helicobacter heilmannii and Helicobacter felis in man or animals.

33. Method for the production of a pharmaceutical composition according to claim 6, characterised by culturing a transformed micro-organism according to claim 16, and optionally, also a micro-organism according to claim 26, collecting and purifying the Helicobacter urease polypeptide material and where applicable, also the HSP material, and combining these materials with suitable excipients, adjuvants and, optionally, other additives.

34. Use of nucleotide sequences of any claim 15 or 25 for the in vitro detection in a biological sample, of an infection by Helicobacter, optionally following a gene amplification reaction.

35. Kit for the in vitro detection of Helicobacter infection, characterised in that it comprises :

- a nucleotide probe according to claim 15 or 25 ;

- an appropriate medium for carrying out a hybridisation reaction between the nucleic acid of Helicobacter and the probe ;

This Sheet Has Been Replaced

106

- reagents for the detection of any hybrids formed.

36. Proteinaceous material characterised in that it comprises a fusion or mixed protein including at least one sub-unit of a urease structural polypeptide from Helicobacter pylori or fragment thereof, or from Helicobacter felis or fragment thereof as defined in claims 1 to 3, 5, 7 to 9, and or a heat shock proteins (HSP) from Helicobacter or fragment thereof, as defined in claims 17 to 20.

37. Purified antibodies or serum obtained by immunisation of an animal with the immunogenic composition according to claims 1 to 5, or with the proteinaceous material or fragment of claims 7 to 9 or 17 to 19, or with the fusion or mixed protein of claims 36.

38. Kit comprising at least the purified antibodies or serum according to claim 37, and optionally, appropriate media or excipients for administration of the antibodies, or labelling or detection means for the antibodies.
