[859] In some embodiments of methods of treating a subject identified as having cancer, any of the variety of therapeutic interventions described herein (e.g., surgery, chemotherapy, hormone therapy, targeted therapy, radiation therapy, and combinations thereof) can be administered to the subject.

[860] In some embodiments, provided herein are methods of identifying a subject as having cancer that include: detecting the presence of one or more genetic biomarkers in circulating DNA in a blood sample obtained from said subject; detecting the presence of an elevated level of one or more peptide biomarkers in the blood sample obtained from a subject; and identifying the subject as having cancer when the presence of one or more genetic biomarkers is detected in circulating DNA in said blood sample, when an elevated level of one or more peptide biomarkers is detected in said blood sample, or both. In some embodiments, provided herein are methods of treating a subject having cancer that include: detecting the presence of one or more genetic biomarkers in circulating DNA in a blood sample obtained from said subject; detecting the presence of an elevated level of one or more peptide biomarkers in the blood sample obtained from a subject; and administering one or more therapeutic interventions (e.g., one or more of surgery, chemotherapy, hormone therapy, targeted therapy, and radiation therapy) to said subject when the presence of one or more genetic biomarkers is detected in circulating DNA in said blood sample, when an elevated

level of one or more peptide biomarkers is detected in said blood sample, or both. In some embodiments, provided herein are methods of identifying the location of a cancer in a subject, said method comprising: detecting the presence of one or more genetic biomarkers in circulating DNA in a blood sample obtained from said subject; detecting the presence of an elevated level of one or more peptide biomarkers in the blood sample obtained from a subject; and identifying the location of the cancer in the subject when the presence of one or more genetic biomarkers is detected in circulating DNA in said blood sample, when an elevated level of one or more peptide biomarkers is detected in said blood sample, or both.

[861] In some embodiments of identifying a subject as having cancer, treating a subject having cancer, or identifying the location of a cancer in a subject (e.g., based on the presence of one or more genetic biomarkers in circulating DNA in a blood sample obtained from said subject and/or presence of an elevated level of one or more peptide biomarkers in the blood sample obtained from a subject), the subject is a human. In some embodiments of identifying a subject as having cancer, treating a subject having cancer, or identifying the location of a cancer in a subject, said blood sample is a plasma sample. In some embodiments of identifying a subject as having cancer, treating a subject having cancer, or identifying the location of a cancer in a subject, the cancer is a Stage I cancer. In some embodiments of identifying a subject as having cancer, treating a subject having cancer, or identifying the location of a cancer in a subject, the one or more genetic biomarkers comprise one or more modifications in one or more genes. In some embodiments of identifying a subject as having cancer, treating a subject having cancer, or identifying the location of a cancer in a subject, the one or more modifications comprise inactivating modifications, and wherein said one or more genes comprise tumor suppressor genes. In some embodiments of identifying a subject as having cancer, treating a subject having cancer, or identifying the location of a cancer in a subject, the one or more modifications include a modification independently selected from single base substitutions, insertions, or deletions, translocations, fusions, breaks, duplications, or amplifications.

[862] In some embodiments of identifying a subject as having cancer, treating a subject having cancer, or identifying the location of a cancer in a subject (e.g., based on the presence of one or more genetic biomarkers in circulating DNA in a blood sample obtained from said

subject and/or presence of an elevated level of one or more peptide biomarkers in the blood sample obtained from a subject), the cancer is liver cancer, ovary cancer, esophageal cancer, stomach cancer, pancreatic cancer, colorectal cancer, lung cancer, breast cancer, or prostate cancer. In some embodiments of identifying a subject as having cancer, treating a subject having cancer, or identifying the location of a cancer in a subject in which the cancer is liver cancer, ovary cancer, esophageal cancer, stomach cancer, pancreatic cancer, colorectal cancer, lung cancer, breast cancer, or prostate cancer and in which the one or more genetic biomarkers are genes, the one or more genes are one or more of: NRAS, CTNNB1, PIK3CA, FBXW7, APC, EGFR, BRAF, CDKN2A, PTEN, FGFR2, HRAS, KRAS, AKT1, TP53, PPP2R1A, or GNAS. In some embodiments of identifying a subject as having cancer, treating a subject having cancer, or identifying the location of a cancer in a subject in which the one or more genes one or more of: NRAS, CTNNB1, PIK3CA, FBXW7, APC, EGFR, BRAF, CDKN2A, PTEN, FGFR2, HRAS, KRAS, AKT1, TP53, PPP2R1A, or GNAS, the one or more protein biomarkers are one or more of CA19-9, CEA, HGF, OPN, CA125, prolactin, TIMP-1, or myeloperoxidase (MPO). In some embodiments of identifying a subject as having cancer, treating a subject having cancer, or identifying the location of a cancer in a subject in which the one or more genes one or more of: NRAS, CTNNB1, PIK3CA, FBXW7, APC, EGFR, BRAF, CDKN2A, PTEN, FGFR2, HRAS, KRAS, AKT1, TP53, PPP2R1A, or GNAS, the one or more protein biomarkers are one or more of CA19-9, CEA, HGF, OPN, CA125, AFP, prolactin, TIMP-1, follistatin, G-CSF, or CA15-3. In some embodiments of identifying a subject as having cancer, treating a subject having cancer, or identifying the location of a cancer in a subject in which the one or more genes one or more of: NRAS, CTNNB1, PIK3CA, FBXW7, APC, EGFR, BRAF, CDKN2A, PTEN, FGFR2, HRAS, KRAS, AKT1, TP53, PPP2R1A, or GNAS, the one or more protein biomarkers are one or more of CA19-9, CEA, HGF, OPN, CA125, AFP, prolactin, TIMP-1, or CA15-3. In some embodiments of identifying a subject as having cancer, treating a subject having cancer, or identifying the location of a cancer in a subject in which the one or more genes one or more of: NRAS, CTNNB1, PIK3CA, FBXW7, APC, EGFR, BRAF, CDKN2A, PTEN, FGFR2, HRAS, KRAS, AKT1, TP53, PPP2R1A, or GNAS, the one or more modifications are independently selected from the modifications set forth in Table 3.

[863] In some embodiments of identifying a subject as having cancer, treating a subject having cancer, or identifying the location of a cancer in a subject (e.g., based on the presence of one or more genetic biomarkers in circulating DNA in a blood sample obtained from said subject and/or presence of an elevated level of one or more peptide biomarkers in the blood sample obtained from a subject), the cancer is pancreatic cancer. In some embodiments of identifying a subject as having cancer, treating a subject having cancer, or identifying the location of a cancer in a subject in which the cancer is pancreatic cancer and in which the one or more genetic biomarkers are genes, the one or more genes are one or more of KRAS, TP53, CDKN2A, or SMAD4. In some embodiments of identifying a subject as having cancer, treating a subject having cancer, or identifying the location of a cancer in a subject in which the one or more genes one or more of: KRAS, TP53, CDKN2A, or SMAD4, the one or more protein biomarkers are one or more of CA19-9, CEA, HGF, or OPN.

[864] In some embodiments of identifying a subject as having cancer, treating a subject having cancer, or identifying the location of a cancer in a subject (e.g., based on the presence of one or more genetic biomarkers in circulating DNA in a blood sample obtained from said subject and/or presence of an elevated level of one or more peptide biomarkers in the blood sample obtained from a subject), the step of detecting the presence of one or more genetic biomarkers is performed using a method that includes a PCR-based multiplex assay, using a PCR-based singleplex assay, a digital PCR assay, a droplet digital PCR (ddPCR) assay, a microarray assay, a next-generation sequencing assay, a Sanger sequencing assay, a quantitative PCR assay, or a ligation assay. In some embodiments, the multiplex PCR-based sequencing assay includes: a. assigning a unique identifier (UID) to each of a plurality of template molecules present in the sample; b. amplifying each uniquely tagged template molecule to create UID-families; and c. redundantly sequencing the amplification products.

[865] In some embodiments of identifying a subject as having cancer, treating a subject having cancer, or identifying the location of a cancer in a subject (e.g., based on the presence of one or more genetic biomarkers in circulating DNA in a blood sample obtained from said subject and/or presence of an elevated level of one or more peptide biomarkers in the blood sample obtained from a subject), the step of elevated level of one or more protein biomarkers is performed using a multiplex immunoassay system.

[866] In some embodiments of identifying a subject as having cancer, the methods further include identifying a location of the cancer. In some embodiments of identifying a subject as having cancer, the methods further include administering to the subject one or more therapeutic interventions. In some embodiments, the one or more therapeutic interventions are one or more of: surgery, chemotherapy, hormone therapy, targeted therapy, or radiation therapy.

[867] In some embodiments of identifying a subject as having cancer, treating a subject having cancer, or identifying the location of a cancer in a subject (e.g., based on the presence of one or more genetic biomarkers in circulating DNA in a blood sample obtained from said subject and/or presence of an elevated level of one or more peptide biomarkers in the blood sample obtained from a subject), the methods further include: a) determining a mutation allele frequency in the blood sample for two or more of the genetic biomarkers; b) obtaining a score that indicates the likelihood that the subject has a cancer by comparing the mutation allele frequency of each mutation in the selected genetic biomarkers to a first reference distribution of mutation allele frequency in control samples and a second reference distribution of mutation allele frequency in samples collected from subjects having a cancer; and c) identifying the subject as having a cancer when the score is higher than a reference value for the score. In some embodiments, obtaining the score includes calculating the ratio of the probability of the mutation allele frequency in the first reference distribution to the probability of the mutation allele frequency in the second reference distribution for each mutation in the selected genetic biomarkers. In some embodiments, the score is determined by calculating the weighted average of the log ratio of the probability of the mutation allele frequency in the first reference distribution to the probability of the mutation allele frequency in the second reference distribution for each mutation in the selected genetic biomarkers. In some embodiments, detecting the presence of one or more genetic biomarkers is performed in two or more test samples using an assay comprising: a. assigning a unique identifier (UID) to each of a plurality of template molecules present in the sample; b. amplifying each uniquely tagged template molecule to create UID-families; and c. redundantly sequencing the amplification products. In some embodiments, the score is calculated by the following formula:

$$\Omega = \sum_{i=1} w_i * ln \frac{p_i^C}{p_i^N}$$

,

wherein w_i is the number of unique identifier sequences (UIDs) in a test sample i divided by the total number of UIDs for that mutation in all test samples, pi^N is the probability of the mutation allele frequency in the first reference distribution, and pi^C is the probability of the mutation allele frequency in the second reference distribution.

[868] In some embodiments of identifying a subject as having cancer, treating a subject having cancer, or identifying the location of a cancer in a subject (e.g., based on the presence of one or more genetic biomarkers in circulating DNA in a blood sample obtained from said subject and/or presence of an elevated level of one or more peptide biomarkers in the blood sample obtained from a subject), the sensitivity of identifying a subject as having cancer is increased as compared to: 1) the sensitivity obtained when the presence of one or more members of only a single class of biomarkers in the sample obtained from the subject is detected. In some embodiments of identifying a subject as having cancer, treating a subject having cancer, or identifying the location of a cancer in a subject, the specificity of identifying a subject as having cancer is increased as compared to: 1) the specificity obtained when the presence of one or more members of only a single class of biomarkers in the sample obtained from the subject is detected.

[869] In some embodiments of identifying a subject as having cancer, treating a subject having cancer, or identifying the location of a cancer in a subject (e.g., based on the presence of one or more genetic biomarkers in circulating DNA in a blood sample obtained from said subject and/or presence of an elevated level of one or more peptide biomarkers in the blood sample obtained from a subject), the methods further include: detecting the presence of aneuploidy in the sample obtained from the subject, wherein the subject is identified as having cancer when the presence of one or more members of the first class of biomarkers are detected in the sample, the presence of one or more members of the second class of biomarkers are detected in the sample, the presence aneuploidy is detected in the sample, or combinations thereof.

[870] In some embodiments, provided herein are method of identifying a patient as having a cancer that include: a) determining a mutation allele frequency in a sample collected from the patient for each mutation in one or more of the following genes: NRAS, CTNNB1, PIK3CA, FBXW7, APC, EGFR, BRAF, CDKN2A, PTEN, FGFR2, HRAS, KRAS, AKT1, TP53, PPP2R1A, or GNAS; b) obtaining a score that indicates the likelihood that the patient has a cancer by comparing the mutation allele frequency of each mutation in the selected genes to a first reference distribution of mutation allele frequency in control samples and a second reference distribution of mutation allele frequency in samples collected from patients having a cancer; and c) identifying the patient as having a cancer when the score is higher than a reference value for the score is higher than a reference value for the score. In some embodiments, such methods further include measuring the concentration of one or more of the following proteins: CA19-9, CEA, HGF, OPN, CA125, prolactin, TIMP-1, or myeloperoxidase (MPO) and determining that the concentration of at least one protein is higher than a reference value. In some embodiments, such methods further include measuring the concentration of one or more of the following proteins: CA19-9, CEA, HGF, OPN, CA125, AFP, prolactin, TIMP-1, follistatin, G-CSF, or CA15-3 and determining that the concentration of at least one protein is higher than a reference value. In some embodiments, such methods further include measuring the concentration of one or more of the following proteins: CA19-9, CEA, HGF, OPN, CA125, AFP, prolactin, TIMP-1, or CA15-3 and determining that the concentration of at least one protein is higher than a reference value. In some embodiments, obtaining the score comprises calculating the ratio of the probability of the mutation allele frequency in the first reference distribution to the probability of the mutation allele frequency in the second reference distribution for each mutation in the selected genes. In some embodiments, the score is determined by calculating the weighted average of the log ratio of the probability of the mutation allele frequency in the first reference distribution to the probability of the mutation allele frequency in the second reference distribution for each mutation in the selected genes. In some embodiments, the sample is assayed in two or more test samples using a method that includes: a. assigning a unique identifier (UID) to each of a plurality of template molecules present in the sample; b. amplifying each uniquely tagged template molecule to create UID-families; and c.

redundantly sequencing the amplification products. In some embodiments, the score is calculated by the following formula:

$$\Omega = \sum_{i=1} w_i * ln \frac{p_i^C}{p_i^N}$$

,

wherein w_i is the number of unique identifier sequences (UIDs) in a test sample i divided by the total number of UIDs for that mutation in all test samples, pi^N is the probability of the mutation allele frequency in the first reference distribution, and pi^C is the probability of the mutation allele frequency in the second reference distribution. In some embodiments, the blood sample is a plasma sample. In some embodiments, the cancer is a Stage I cancer. In some embodiments, the cancer is liver cancer, ovary cancer, esophageal cancer, stomach cancer, pancreatic cancer, colorectal cancer, lung cancer, breast cancer, or prostate cancer. In some embodiments, the at least one mutation comprises an inactivating modifications, and wherein the at least one mutation is in a tumor suppressor gene. In some embodiments, the at least one mutation comprises a mutation that is a single base substitution, an insertion, or a deletion. In some embodiments, the at least one mutation is a mutation set forth in Table 3. In some embodiments, the step of detecting the level of one or more proteins is performed using a multiplex immunoassay system. In some embodiments, the methods further include identifying a location of the cancer. In some embodiments, the methods further include comprising administering to the mammal one or more therapeutic interventions. In some embodiments, the one or more therapeutic interventions are one or more of: surgery, chemotherapy, hormone therapy, targeted therapy, or radiation therapy.

[871] In some embodiments, provided herein are method of identifying a patient as having a cancer that include: a) determining a mutation allele frequency in a sample collected from the patient for each mutation in one or more of the following genes: KRAS, TP53, CDKN2A, or SMAD4; b) obtaining a score that indicates the likelihood that the patient has a cancer by comparing the mutation allele frequency of each mutation in the selected genes to a first reference distribution of mutation allele frequency in control samples and a second reference distribution of mutation allele frequency in samples collected from patients having a cancer;

and c) identifying the patient as having a cancer when the score is higher than a reference value for the score is higher than a reference value for the score. In some embodiments, such methods further include measuring the concentration of one or more of the following proteins: CA19-9, CEA, HGF, or OPN and determining that the concentration of at least one protein is higher than a reference value. In some embodiments, obtaining the score comprises calculating the ratio of the probability of the mutation allele frequency in the first reference distribution to the probability of the mutation allele frequency in the second reference distribution for each mutation in the selected genes. In some embodiments, the score is determined by calculating the weighted average of the log ratio of the probability of the mutation allele frequency in the first reference distribution to the probability of the mutation allele frequency in the second reference distribution for each mutation in the selected genes. In some embodiments, the sample is assayed in two or more test samples using a method that includes: a. assigning a unique identifier (UID) to each of a plurality of template molecules present in the sample; b. amplifying each uniquely tagged template molecule to create UID-families; and c. redundantly sequencing the amplification products. In some embodiments, the score is calculated by the following formula:

$$\Omega = \sum_{i=1} w_i * ln \frac{p_i^C}{p_i^N}$$

,

wherein w_i is the number of unique identifier sequences (UIDs) in a test sample i divided by the total number of UIDs for that mutation in all test samples, pi^N is the probability of the mutation allele frequency in the first reference distribution, and pi^C is the probability of the mutation allele frequency in the second reference distribution. In some embodiments, the blood sample is a plasma sample. In some embodiments, the cancer is a Stage I cancer. In some embodiments, the cancer is liver cancer, ovary cancer, esophageal cancer, stomach cancer, pancreatic cancer, colorectal cancer, lung cancer, breast cancer, or prostate cancer. In some embodiments, the at least one mutation comprises an inactivating modifications, and wherein the at least one mutation is in a tumor suppressor gene. In some embodiments, the at least one mutation comprises a mutation that is a single base substitution, an insertion, or a

deletion. In some embodiments, the step of detecting the level of one or more proteins is performed using a multiplex immunoassay system. In some embodiments, the methods further include identifying a location of the cancer. In some embodiments, the methods further include comprising administering to the mammal one or more therapeutic interventions. In some embodiments, the one or more therapeutic interventions are one or more of: surgery, chemotherapy, hormone therapy, targeted therapy, or radiation therapy.

[872] In some embodiments, provided herein are systems for generating a report for a patient that include: at least one device configured to assay a set of genes in a biological sample to determine mutation allele frequency of each mutation in the set of genes in a sample collected from the patient, wherein the set of genes comprises one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 16, or 16) of the following genes: NRAS, CTNNB1, PIK3CA, FBXW7, APC, EGFR, BRAF, CDKN2A, PTEN, FGFR2, HRAS, KRAS, AKT1, TP53, PPP2R1A, and/or GNAS; b) at least one computer database including: i) a first reference distribution of mutation allele frequency in control samples for each mutation in the set of genes; and ii) a second reference distribution of mutation allele frequency in samples collected from patients having a cancer for each mutation in the set of genes; c) a computer-readable program code comprising instructions to execute the following: i) inputting the mutation allele frequency in the biological sample of each mutation in the set of genes; ii) comparing the mutation allele frequency to the first reference distribution; iii) comparing the mutation allele frequency to the second reference distribution; and iv) calculating a score that indicates the likelihood that the patient has a cancer; d) a computer-readable program code comprising instructions to generate a report that indicates the patient as having a cancer if the score is higher than a reference value; or a report that indicates the patient as not having a cancer if the score is not higher than the reference value.

[873] In some embodiments, provided herein are systems for generating a report for a patient that include: at least one device configured to assay a set of genes in a biological sample to determine mutation allele frequency of each mutation in the set of genes in a sample collected from the patient, wherein the set of genes comprises one or more (e.g., 1, 2, 3, or 4) of the following genes: KRAS, TP53, CDKN2A, and/or SMAD4; b) at least one computer database including: i) a first reference distribution of mutation allele frequency in

control samples for each mutation in the set of genes; and ii) a second reference distribution of mutation allele frequency in samples collected from patients having a cancer for each mutation in the set of genes; c) a computer-readable program code comprising instructions to execute the following: i) inputting the mutation allele frequency in the biological sample of each mutation in the set of genes; ii) comparing the mutation allele frequency to the first reference distribution; iii) comparing the mutation allele frequency to the second reference distribution; and iv) calculating a score that indicates the likelihood that the patient has a cancer; d) a computer-readable program code comprising instructions to generate a report that indicates the patient as having a cancer if the score is higher than a reference value; or a report that indicates the patient as not having a cancer if the score is not higher than the reference value.

[874] In some embodiments, provided herein are systems for generating a report to identify a cancer treatment for a patient that include: a) at least one device configured to assay a set of genes in a biological sample to determine mutation allele frequency of each mutation in the set of genes in a sample collected from the patient, wherein the set of genes comprises one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 16, or 16) of the following genes: NRAS, CTNNB1, PIK3CA, FBXW7, APC, EGFR, BRAF, CDKN2A, PTEN, FGFR2, HRAS, KRAS, AKT1, TP53, PPP2R1A, and/or GNAS; b) at least one computer database comprising: i) a first reference distribution of mutation allele frequency in control samples for each mutation in the set of genes; ii) a second reference distribution of mutation allele frequency in samples collected from patients having a cancer for each mutation in the set of genes; and iii) a listing of cancer treatment with efficacy linked to a biological state of at least one member of the set of genes; c) a computer-readable program code comprising instructions to execute the following: i) inputting the mutation allele frequency in the biological sample of each mutation in the set of genes; ii) comparing the mutation allele frequency to the first reference distribution; iii) comparing the mutation allele frequency to the second reference distribution; and iv) calculating a score that indicates the likelihood that the patient has a cancer; d) a computer-readable program code comprising instructions to generate a report that indicates the patient as having a cancer if the score is higher than a reference value; or a report that indicates the patient as not having a cancer if the score is not

higher than the reference value; and e) a computer-readable program code comprising instructions to identify for the patient at least one cancer treatment from the listing of cancer treatments in (b)(iii) when the patient is identified as having a cancer in step (d), wherein the calculated score provides an indication that the identified cancer treatment will be effective in the patient.

[875] In some embodiments, provided herein are systems for generating a report to identify a cancer treatment for a patient that include: a) at least one device configured to assay a set of genes in a biological sample to determine mutation allele frequency of each mutation in the set of genes in a sample collected from the patient, wherein the set of genes comprises one or more (e.g., 1, 2, 3, or 4) of the following genes: KRAS, TP53, CDKN2A, and/or SMAD4; b) at least one computer database comprising: i) a first reference distribution of mutation allele frequency in control samples for each mutation in the set of genes; ii) a second reference distribution of mutation allele frequency in samples collected from patients having a cancer for each mutation in the set of genes; and iii) a listing of cancer treatment with efficacy linked to a biological state of at least one member of the set of genes; c) a computer-readable program code comprising instructions to execute the following: i) inputting the mutation allele frequency in the biological sample of each mutation in the set of genes; ii) comparing the mutation allele frequency to the first reference distribution; iii) comparing the mutation allele frequency to the second reference distribution; and iv) calculating a score that indicates the likelihood that the patient has a cancer; d) a computer-readable program code comprising instructions to generate a report that indicates the patient as having a cancer if the score is higher than a reference value; or a report that indicates the patient as not having a cancer if the score is not higher than the reference value; and e) a computer-readable program code comprising instructions to identify for the patient at least one cancer treatment from the listing of cancer treatments in (b)(iii) when the patient is identified as having a cancer in step (d), wherein the calculated score provides an indication that the identified cancer treatment will be effective in the patient.

[876] In some embodiments, provided herein are systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both that include: a) at least one device configured to assay a set of genes in a

biological sample to determine mutation allele frequency of each mutation in the set of genes in a sample collected from the patient, wherein the set of genes comprises one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 16, or 16) of the following genes: NRAS, CTNNB1, PIK3CA, FBXW7, APC, EGFR, BRAF, CDKN2A, PTEN, FGFR2, HRAS, KRAS, AKT1, TP53, PPP2R1A, and/or GNAS; b) at least one computer database comprising: i) a first reference distribution of mutation allele frequency in control samples for each mutation in the set of genes; ii) a second reference distribution of mutation allele frequency in samples collected from patients having a cancer for each mutation in the set of genes; and iii) a listing of cancer treatment with efficacy linked to a biological state of at least one member of the set of genes; c) a computer-readable program code comprising instructions to execute the following: i) inputting the mutation allele frequency in the biological sample of each mutation in the set of genes; ii) comparing the mutation allele frequency to the first reference distribution; iii) comparing the mutation allele frequency to the second reference distribution; and iv) calculating a score that indicates the likelihood that the patient has a cancer; d) a computer-readable program code comprising instructions to generate a report that indicates the patient as having a cancer if the score is higher than a reference value; or a report that indicates the patient as not having a cancer if the score is not higher than the reference value; and e) a computer-readable program code comprising instructions to identify for the patient at least one cancer treatment from the listing of cancer treatments in (b)(iii) when the patient is identified as having a cancer in step (d), wherein the calculated score provides an indication that the identified cancer treatment will be effective in the patient.

[877] In some embodiments, provided herein are systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both that include: a) at least one device configured to assay a set of genes in a biological sample to determine mutation allele frequency of each mutation in the set of genes in a sample collected from the patient, wherein the set of genes comprises one or more (e.g., 1, 2, 3, or 4) of the following genes: KRAS, TP53, CDKN2A, and/or SMAD4; b) at least one computer database comprising: i) a first reference distribution of mutation allele frequency in control samples for each mutation in the set of genes; ii) a second reference distribution of mutation allele frequency in samples collected from patients having a cancer for each

mutation in the set of genes; and iii) a listing of cancer treatment with efficacy linked to a biological state of at least one member of the set of genes; c) a computer-readable program code comprising instructions to execute the following: i) inputting the mutation allele frequency in the biological sample of each mutation in the set of genes; ii) comparing the mutation allele frequency to the first reference distribution; iii) comparing the mutation allele frequency to the second reference distribution; and iv) calculating a score that indicates the likelihood that the patient has a cancer; d) a computer-readable program code comprising instructions to generate a report that indicates the patient as having a cancer if the score is higher than a reference value; or a report that indicates the patient as not having a cancer if the score is not higher than the reference value; and e) a computer-readable program code comprising instructions to identify for the patient at least one cancer treatment from the listing of cancer treatments in (b)(iii) when the patient is identified as having a cancer in step (d), wherein the calculated score provides an indication that the identified cancer treatment will be effective in the patient.

[878] In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, calculating the score comprises calculating the ratio of the probability of the mutation allele frequency in the first reference distribution to the probability of the mutation allele frequency in the second reference distribution for each mutation in the selected genes. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the score is calculated by calculating the weighted average of the log ratio of the probability of the mutation allele frequency in the first reference distribution to the probability of the mutation allele frequency in the second reference distribution for each mutation in the selected genes. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the

computer database comprises test sample data, the test sample data includes assignment of a unique identifier (UID) to each of a plurality of template molecules present in the sample. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the score is calculated by the following formula:

$$\Omega = \sum_{i=1} w_i * ln \frac{p_i^C}{p_i^N}$$

,

wherein w_i is the number of unique identifier sequences (UIDs) in a test sample i divided by the total number of UIDs for that mutation in all test samples, pi^N is the probability of the mutation allele frequency in the first reference distribution, and pi^C is the probability of the mutation allele frequency in the second reference distribution. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the device configured to assay a set of genes comprises a device that employs a includes a PCR-based multiplex assay, using a PCR-based singleplex assay, a digital PCR assay, a droplet digital PCR (ddPCR) assay, a microarray assay, a next-generation sequencing assay, a Sanger sequencing assay, a quantitative PCR assay, or a ligation assay. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the multiplex PCR-based sequencing assay comprises: a. assigning a unique identifier (UID) to each of a plurality of template molecules present in the sample; b. amplifying each uniquely tagged template molecule to create UID-families; and c. redundantly sequencing the amplification products. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased

monitoring, further diagnostic testing, or both, the system further includes a device (e.g., a device that includes a multiplex immunoassay system) configured to detect a level of one or more protein biomarkers in a biological sample, wherein the protein biomarkers are one or more (e.g., 1, 2, 3, 4, 5, 6, 7, or 8) of: CA19-9, CEA, HGF, OPN, CA125, prolactin, TIMP-1, and/or myeloperoxidase (MPO). In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the system further includes a device (e.g., a device that includes a multiplex immunoassay system) configured to detect a level of one or more protein biomarkers in a biological sample, wherein the protein biomarkers are one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, or 11) of: CA19-9, CEA, HGF, OPN, CA125, AFP, prolactin, TIMP-1, follistatin, G-CSF, and/or CA15-3. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the system further includes a device (e.g., a device that includes a multiplex immunoassay system) configured to detect a level of one or more protein biomarkers in a biological sample, wherein the protein biomarkers are one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, or 9) of: CA19-9, CEA, HGF, OPN, CA125, AFP, prolactin, TIMP-1, and/or CA15-3. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both that include at least one device configured to assay one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 16, or 16) of the following genes: NRAS, CTNNB1, PIK3CA, FBXW7, APC, EGFR, BRAF, CDKN2A, PTEN, FGFR2, HRAS, KRAS, AKT1, TP53, PPP2R1A, and/or GNAS, the system further includes a device (e.g., a device that includes a multiplex immunoassay system) configured to detect a level of one or more protein biomarkers in a biological sample, wherein the protein biomarkers are one or more (e.g., 1, 2, 3, 4, 5, 6, 7, or 8) of: CA19-9, CEA, HGF, OPN, CA125, prolactin, TIMP-1, and/or myeloperoxidase (MPO). In some embodiments of systems for generating a report for a patient, systems for

generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both that include at least one device configured to assay one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 16, or 16) of the following genes: NRAS, CTNNB1, PIK3CA, FBXW7, APC, EGFR, BRAF, CDKN2A, PTEN, FGFR2, HRAS, KRAS, AKT1, TP53, PPP2R1A, and/or GNAS, the system further includes a device (e.g., a device that includes a multiplex immunoassay system) configured to detect a level of one or more protein biomarkers in a biological sample, wherein the protein biomarkers are one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, or 11) of: CA19-9, CEA, HGF, OPN, CA125, AFP, prolactin, TIMP-1, follistatin, G-CSF, and/or CA15-3. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both that include at least one device configured to assay one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 16, or 16) of the following genes: NRAS, CTNNB1, PIK3CA, FBXW7, APC, EGFR, BRAF, CDKN2A, PTEN, FGFR2, HRAS, KRAS, AKT1, TP53, PPP2R1A, and/or GNAS, the system further includes a device (e.g., a device that includes a multiplex immunoassay system) configured to detect a level of one or more protein biomarkers in a biological sample, wherein the protein biomarkers are one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, or 9) of: CA19-9, CEA, HGF, OPN, CA125, AFP, prolactin, TIMP-1, and/or CA15-3. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the system further includes a device (e.g., a device that includes a multiplex immunoassay system) configured to detect a level of one or more protein biomarkers in a biological sample, wherein the protein biomarkers are one or more (e.g., 1, 2, 3, or 4) of: CA19-9, CEA, HGF, and/or OPN. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both that include at least one device

configured to assay one or more (e.g., 1, 2, 3, or 4) of the following genes: KRAS, TP53, CDKN2A, and/or SMAD4, the system further includes a device (e.g., a device that includes a multiplex immunoassay system) configured to detect a level of one or more protein biomarkers in a biological sample, wherein the protein biomarkers are one or more (e.g., 1, 2, 3, or 4) of: CA19-9, CEA, HGF, and/or OPN. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the sensitivity of the system in identifying a subject as having cancer is improved as compared to conventional systems for generating a report for a patient. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the specificity of the system in identifying a subject as having cancer is improved as compared to conventional systems for generating a report for a patient. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the first and second reference distribution of mutation allele frequency values are input into the system from a location that is remote from the at least one computer database. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, first and second reference distribution of mutation allele frequency values are input into the system over an internet connection. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the report is in electronic or paper format. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a

patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the cancer is any of the variety of cancer types described herein (see, e.g., section entitled "Cancers"). In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both that include at least one device configured to assay one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 16, or 16) of the following genes: NRAS, CTNNB1, PIK3CA, FBXW7, APC, EGFR, BRAF, CDKN2A, PTEN, FGFR2, HRAS, KRAS, AKT1, TP53, PPP2R1A, and/or GNAS and at least one a device (e.g., a device that includes a multiplex immunoassay system) configured to detect a level of one or more protein biomarkers in a biological sample, wherein the protein biomarkers are one or more (e.g., 1, 2, 3, 4, 5, 6, 7, or 8) of: CA19-9, CEA, HGF, OPN, CA125, prolactin, TIMP-1, and/or myeloperoxidase (MPO), the cancer is liver cancer, ovary cancer, esophageal cancer, stomach cancer, pancreatic cancer, colorectal cancer, lung cancer, breast cancer, or prostate cancer. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both that include at least one device configured to assay one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 16, or 16) of the following genes: NRAS, CTNNB1, PIK3CA, FBXW7, APC, EGFR, BRAF, CDKN2A, PTEN, FGFR2, HRAS, KRAS, AKT1, TP53, PPP2R1A, and/or GNAS and at least one a device (e.g., a device that includes a multiplex immunoassay system) configured to detect a level of one or more protein biomarkers in a biological sample, wherein the protein biomarkers are one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, or 11) of: CA19-9, CEA, HGF, OPN, CA125, AFP, prolactin, TIMP-1, follistatin, G-CSF, and/or CA15-3, the cancer is liver cancer, ovary cancer, esophageal cancer, stomach cancer, pancreatic cancer, colorectal cancer, lung cancer, breast cancer, or prostate cancer. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both that include at least one device

configured to assay one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 16, or 16) of the following genes: NRAS, CTNNB1, PIK3CA, FBXW7, APC, EGFR, BRAF, CDKN2A, PTEN, FGFR2, HRAS, KRAS, AKT1, TP53, PPP2R1A, and/or GNAS and at least one a device (e.g., a device that includes a multiplex immunoassay system) configured to detect a level of one or more protein biomarkers in a biological sample, wherein the protein biomarkers are one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, or 9) of: CA19-9, CEA, HGF, OPN, CA125, AFP, prolactin, TIMP-1, and/or CA15-3, the cancer is liver cancer, ovary cancer, esophageal cancer, stomach cancer, pancreatic cancer, colorectal cancer, lung cancer, breast cancer, or prostate cancer. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both that include at least one device configured to assay one or more (e.g., 1, 2, 3, or 4) of the following genes: KRAS, TP53, CDKN2A, and/or SMAD4 and at least one a device (e.g., a device that includes a multiplex immunoassay system) configured to detect a level of one or more protein biomarkers in a biological sample, wherein the protein biomarkers are one or more (e.g., 1, 2, 3, or 4) of: CA19-9, CEA, HGF, and/or OPN, the cancer is pancreatic cancer. In some embodiments of systems for generating a report for a patient or systems for generating a report to identify a cancer treatment for a patient, the patient is identified as a candidate for increased monitoring, further diagnostic testing, or both (e.g. any of the variety of increased monitoring or further diagnostic methods described herein).

[879] In some embodiments, provided herein are methods of identifying a subject as having cancer that include: detecting the presence of one or more genetic biomarkers in a first sample obtained from said subject; detecting the presence of aneuploidy in a second sample obtained from said subject; and identifying the subject as having cancer when the presence of one or more genetic biomarkers is detected in the first sample, when the presence of aneuploidy is detected in the second sample, or both. In some embodiments, provided herein are methods of treating a subject having cancer that include: detecting the presence of one or more genetic biomarkers in a first sample obtained from said subject; detecting the presence of aneuploidy in a second sample obtained from said subject; and administering one or more

therapeutic interventions to said subject when the presence of one or more genetic biomarkers is detected in the first sample, when the presence of aneuploidy is detected in the second sample, or both.

[880] In some embodiments of identifying a subject as having cancer or treating a subject having cancer (e.g., based on the presence of one or more genetic biomarkers in a first sample obtained from said subject and/or the presence of aneuploidy in a second sample obtained from the subject), the step of detecting the presence of one or more genetic biomarkers comprises a method that includes a PCR-based multiplex assay, using a PCR-based singleplex assay, a digital PCR assay, a droplet digital PCR (ddPCR) assay, a microarray assay, a next-generation sequencing assay, a Sanger sequencing assay, a quantitative PCR assay, or a ligation assay. In some embodiments, the step of detecting the presence of one or more genetic biomarkers comprises a method that increases the sensitivity of massively parallel sequencing instruments with an error reduction technique comprising: a. assigning a unique identifier (UID) to each of a plurality of template molecules present in the sample; b. amplifying each uniquely tagged template molecule to create UID-families; and c. redundantly sequencing the amplification products.

[881] In some embodiments of identifying a subject as having cancer or treating a subject having cancer (e.g., based on the presence of one or more genetic biomarkers in a first sample obtained from said subject and/or the presence of aneuploidy in a second sample obtained from the subject), the step of detecting the presence of aneuploidy includes: amplifying long interspersed nucleotide elements (LINEs) across the genome of the second sample, thereby obtaining a plurality of amplicons; sequencing the plurality of amplicons to obtain sequencing reads; placing the sequencing reads into pre-defined clusters of genomic intervals; and determining the presence of aneuploidy in the second sample when the number of sequencing reads of a genomic region within a pre-defined cluster is significantly different from the expected number of sequencing reads of the genomic region within the pre-defined cluster. In some embodiments, the pre-defined clusters of genomic intervals are created by grouping genomic intervals based on read depths of sequencing reads of two or more euploid samples. In some embodiments, determining that the number of sequencing reads of a genomic region within a pre-defined cluster is significantly different from the expected

number of sequencing reads of the genomic region within the pre-defined cluster includes: calculating the distribution of sequencing reads of all genomic intervals in the pre-defined cluster, wherein the sequence reads of all genomic intervals in the pre-defined cluster are obtained by sequencing the amplicons derived from the second sample; and determining the number of sequencing reads of the genomic region is outside a significance threshold of the distribution. In some embodiments, determining that the number of sequencing reads of a genomic region within a pre-defined cluster is significantly different from the expected number of sequencing reads of the genomic region within the pre-defined cluster includes: calculating sums of distributions of the sequencing reads in each genomic interval using the equation $\sum_1^I R_i \sim N(\sum_1^I \mu_i, \sum_1^I \sigma_i^2)$, wherein R_i is the number of sequencing reads, I is the number of clusters on a chromosome arm, N is a Gaussian distribution with parameters μ_i and σ_i^2, where μ_i is the mean number of sequencing reads in each genomic interval, and where σ_i^2 is the variance of sequencing reads in each genomic interval; calculating a Z-score of a chromosome arm using the quantile function 1-CDF($\sum_1^I \mu_i, \sum_1^I \sigma_i^2$); and identifying the presence of an aneuploidy in the tissue of the mammal when the Z-score is outside a significance threshold.

[882] In some embodiments of identifying a subject as having cancer or treating a subject having cancer (e.g., based on the presence of one or more genetic biomarkers in a first sample obtained from said subject and/or the presence of aneuploidy in a second sample obtained from the subject), the step of detecting the presence of aneuploidy includes: sequencing a plurality of amplicons obtained from a second sample to obtain variant sequencing reads for a plurality of polymorphic sites; selecting a chromosome arm having the variant sequencing reads and the reference sequencing reads on both alleles that is greater than about 3; determining a variant-allele frequency (VAF) of each polymorphic site in the selected chromosome arm, wherein said VAF is the number of variant sequencing reads / total number of sequencing reads; and identifying the presence of aneuploidy on the selected chromosome arm if the VAF of one or more polymorphic sites is outside a significance threshold of a normal distribution, wherein the expected VAF is 0.5. In some embodiments, the step of sequencing includes: a. assigning a unique identifier (UID) to each of a plurality of amplicons, b. amplifying each uniquely tagged amplicon to create UID-families, and c.

redundantly sequencing the amplification products. In some embodiments, the step of identifying the presence of aneuploidy on the selected chromosome arm includes: calculating a Z-score for one or more polymorphic sites on said selected chromosome arm using the equation $Z \sim \frac{\sum_{i=1}^{k} w_i Z_i}{\sqrt{\sum_{i=1}^{k} w_i^2}}$, where w_i is UID depth at a variant i, Z_i is the Z-score of VAF for variant i, and k is the number of variants observed on the chromosome arm.

[883] In some embodiments of identifying a subject as having cancer or treating a subject having cancer (e.g., based on the presence of one or more genetic biomarkers in a first sample obtained from said subject and/or the presence of aneuploidy in a second sample obtained from the subject), the methods further include performing cytology on the first sample, the second sample, or both, and identifying the subject as having cancer when the presence of one or more genetic biomarkers is detected in the first sample, when the presence of aneuploidy is detected in the second sample, a positive cytology indicates that the subject has cancer, or combinations thereof.

[884] In some embodiments of identifying a subject as having cancer or treating a subject having cancer (e.g., based on the presence of one or more genetic biomarkers in a first sample obtained from said subject and/or the presence of aneuploidy in a second sample obtained from the subject), the cancer is a bladder cancer or an upper tract urothelial carcinoma; the one or more genetic biomarkers are one or more of: TP53, PIK3CA, FGFR3, KRAS, ERBB2, CDKN2A, MLL, HRAS, MET, or VHL; the method further includes detecting the presence of at least one genetic biomarker (e.g., a mutation) in a TERT promoter; and the presence of one or more genetic biomarkers in one or more of TP53, PIK3CA, FGFR3, KRAS, ERBB2, CDKN2A, MLL, HRAS, MET, and VHL, the presence of the at least one genetic biomarker (e.g., a mutation) in the TERT promoter, or the presence of aneuploidy indicates that the subject has bladder cancer. In some embodiments, the presence of one or more genetic biomarkers in one or more of TP53, PIK3CA, FGFR3, KRAS, ERBB2, CDKN2A, MLL, HRAS, MET, and VHL, the presence of the at least one genetic biomarker (e.g., a mutation) in the TERT promoter, and the presence of aneuploidy indicates that the subject has bladder cancer. In some embodiments, the one or more genetic biomarkers are TP53, FGFR3, or both. In some embodiments, the step of detecting the

presence of aneuploidy comprises detecting the presence of aneuploidy on one or more of chromosome arms 5q, 8q, and 9p. In some embodiments, the one or more genetic biomarkers, the one or more genetic biomarkers (e.g., a mutations) in the TERT promoter, or both, are present in 0.03% or fewer of the urinary cells in the sample. In some embodiments, the step of detecting the presence of at least one genetic biomarker (e.g., a mutation) in the TERT promoter is performed using a PCR based multiplex assay, a Sanger Sequencing assay, or a next generation sequencing assay. In some embodiments, the step of detecting the presence of at least one genetic biomarker (e.g., a mutation) in the TERT promoter is performed by increasing the sensitivity of massively parallel sequencing instruments with an error reduction technique including: a. assigning a unique identifier (UID) to each of a plurality of template molecules present in the sample; b. amplifying each uniquely tagged template molecule to create UID-families; and c. redundantly sequencing the amplification products.

[885] In some embodiments of identifying a subject as having cancer or treating a subject having cancer (e.g., based on the presence of one or more genetic biomarkers in a first sample obtained from said subject and/or the presence of aneuploidy in a second sample obtained from the subject), the method includes detecting bladder cancer and further includes administering transuretral resection of the bladder (TURB), intravesical BCG (Bacillus Calmette-Guerin), intravesical chemotherapy, adjuvant chemotherapy, neoadjuvant chemotherapy, cystectomy or cystoprostatectomy, radiation therapy, immunotherapy, immune checkpoint inhibitors, or any combination thereof.

[886] In some embodiments of identifying a subject as having cancer or treating a subject having cancer (e.g., based on the presence of one or more genetic biomarkers in a first sample obtained from said subject and/or the presence of aneuploidy in a second sample obtained from the subject), the method includes detecting an upper tract urothelial carcinoma and further includes administering transurethral resection, intravesical BCG (Bacillus Calmette-Guerin), intravesical chemotherapy, adjuvant chemotherapy, neoadjuvant chemotherapy, ureterectomy or nephroureterectomy, radiation therapy, immunotherapy, immune checkpoint inhibitors, or any combination thereof.

[887] In some embodiments of identifying a subject as having cancer or treating a subject having cancer (e.g., based on the presence of one or more genetic biomarkers in a first sample obtained from said subject and/or the presence of aneuploidy in a second sample obtained from the subject), the cancer is an ovarian or endometrial cancer; the one or more genetic biomarkers are one or more of NRAS, PTEN, FGFR2, KRAS, POLE, AKT1, TP53, RNF43, PPP2R1A, MAPK1, CTNNB1, PIK3CA, FBXW7, PIK3R1, APC, EGFR, BRAF, or CDKN2A; and the presence of one or more mutations in one or more of NRAS, PTEN, FGFR2, KRAS, POLE, AKT1, TP53, RNF43, PPP2R1A, MAPK1, CTNNB1, PIK3CA, FBXW7, PIK3R1, APC, EGFR, BRAF, or CDKN2A, the presence of aneuploidy, or both indicates that the subject has ovarian or endometrial cancer. In some embodiments of identifying a subject as having cancer or treating a subject having cancer (e.g., based on the presence of one or more genetic biomarkers in a first sample obtained from said subject and/or the presence of aneuploidy in a second sample obtained from the subject), the cancer is an endometrial cancer; the one or more genetic biomarkers are one or more of PTEN, TP53, PIK3CA, PIK3R1, CTNNB1, KRAS, FGFR2, POLE, APC, FBXW7, RNF43, or PPP2R1A; and the presence of one or more mutations in one or more of PTEN, TP53, PIK3CA, PIK3R1, CTNNB1, KRAS, FGFR2, POLE, APC, FBXW7, RNF43, or PPP2R1A, the presence of aneuploidy, or both indicates that the subject has endometrial cancer. In some embodiments of identifying a subject as having cancer or treating a subject having cancer (e.g., based on the presence of one or more genetic biomarkers in a first sample obtained from said subject and/or the presence of aneuploidy in a second sample obtained from the subject), the cancer is a high-grade serous carcinoma; the one or more genetic biomarkers in TP53; and the presence of one or more genetic biomarkers in TP53, the presence of aneuploidy, or both indicates that the subject has a high-grade serous carcinoma. In some embodiments, the step of detecting the presence of aneuploidy includes detecting the presence of aneuploidy on one or more of chromosome arms 4p, 7q, 8q, and 9q. In some embodiments, the first sample, the second sample, or both are collected via intrauterine sampling. In some embodiments, the first sample, the second sample, or both are collected with a Tao brush. In some embodiments, the methods further include detecting in a circulating tumor DNA (ctDNA) sample obtained from the subject the presence of at least

one genetic biomarker in one or more of the following genes: AKT1, APC, BRAF, CDKN2A, CTNNB1, EGFR, FBXW7, FGFR2, GNAS, HRAS, KRAS, NRAS, PIK3CA, PPP2R1A, PTEN, or TP53. In some embodiments, the methods further include administering to the subject a therapy, wherein the therapy includes: surgery, adjuvant chemotherapy, neoadjuvant chemotherapy, radiation therapy, immunotherapy, targeted therapy, immune checkpoint inhibitors, or combinations thereof.

[888] In some embodiments of identifying a subject as having cancer or treating a subject having cancer (e.g., based on the presence of one or more genetic biomarkers in a first sample obtained from said subject and/or the presence of aneuploidy in a second sample obtained from the subject), the genetic biomarker is a mutation in a gene.

[889] In some embodiments of identifying a subject as having cancer or treating a subject having cancer (e.g., based on the presence of one or more genetic biomarkers in a first sample obtained from said subject and/or the presence of aneuploidy in a second sample obtained from the subject), the first sample and the second sample are the same. In some embodiments of identifying a subject as having cancer or treating a subject having cancer (e.g., based on the presence of one or more genetic biomarkers in a first sample obtained from said subject and/or the presence of aneuploidy in a second sample obtained from the subject), the first sample and the second sample are different. In some embodiments of identifying a subject as having cancer or treating a subject having cancer (e.g., based on the presence of one or more genetic biomarkers in a first sample obtained from said subject and/or the presence of aneuploidy in a second sample obtained from the subject), the first sample is a blood sample.

[890] In some embodiments of identifying a subject as having cancer or treating a subject having cancer (e.g., based on the presence of one or more genetic biomarkers in a first sample obtained from said subject and/or the presence of aneuploidy in a second sample obtained from the subject), the methods further include a) determining a mutation allele frequency in the sample for two or more of the genetic biomarkers; b) obtaining a score that indicates the likelihood that the subject has a cancer by comparing the mutation allele frequency of each mutation in the selected genetic biomarkers against a reference distribution

of mutation allele frequency for each mutation in control samples; and c) identifying the subject as having a cancer when the score is higher than a reference value for the score. In some embodiments, the methods further include selecting one genetic biomarker with the highest score that indicates the probability that the subject has a cancer from the two or more genetic biomarkers; and comparing the score for the selected genetic biomarker to the reference value. In some embodiments, the score is Stouffer's Z-score.

[891] In some embodiments of identifying a subject as having cancer or treating a subject having cancer (e.g., based on the presence of one or more genetic biomarkers in a first sample obtained from said subject and/or the presence of aneuploidy in a second sample obtained from the subject), the methods further include a) determining a mutation allele frequency in the sample for two or more of the genetic biomarkers; and b) comparing the mutation allele frequency of each mutation in the selected genetic biomarkers to the maximum mutation allele frequency of each mutation for each mutation in control samples.

[892] In some embodiments of identifying a subject as having cancer or treating a subject having cancer (e.g., based on the presence of one or more genetic biomarkers in a first sample obtained from said subject and/or the presence of aneuploidy in a second sample obtained from the subject), the sensitivity of identifying a subject as having cancer is increased as compared to: 1) the sensitivity obtained when only the presence of one or more genetic biomarkers in the sample obtained from the subject is detected, or 2) the sensitivity obtained when the presence of only aneuploidy in the sample obtained from the subject is detected. In some embodiments of identifying a subject as having cancer or treating a subject having cancer (e.g., based on the presence of one or more genetic biomarkers in a first sample obtained from said subject and/or the presence of aneuploidy in a second sample obtained from the subject), the specificity of identifying a subject as having cancer is increased as compared to: 1) the specificity obtained when only the presence of one or more genetic biomarkers in the sample obtained from the subject is detected, or 2) the specificity obtained when the presence of only aneuploidy in the sample obtained from the subject is detected.

[893] In some embodiments of identifying a subject as having cancer or treating a subject having cancer (e.g., based on the presence of one or more genetic biomarkers in a first

sample obtained from said subject and/or the presence of aneuploidy in a second sample obtained from the subject), the methods further include detecting the presence of a detecting one or more protein biomarkers in a sample obtained from the subject, wherein the sample is the first sample, the second sample, or a third sample. In some embodiments of identifying a subject as having cancer or treating a subject having cancer (e.g., based on the presence of one or more genetic biomarkers in a first sample obtained from said subject and/or the presence of aneuploidy in a second sample obtained from the subject), subject is a human. In some embodiments of identifying a subject as having cancer or treating a subject having cancer (e.g., based on the presence of one or more genetic biomarkers in a first sample obtained from said subject and/or the presence of aneuploidy in a second sample obtained from the subject), the cancer is a Stage I cancer.

[894] In some embodiments of identifying a subject as having cancer or treating a subject having cancer (e.g., based on the presence of one or more genetic biomarkers in a first sample obtained from said subject and/or the presence of aneuploidy in a second sample obtained from the subject), the one or more genetic biomarkers comprise one or more modifications in one or more genes. In some embodiments, the one or more modifications comprise inactivating modifications, and wherein said one or more genes comprise tumor suppressor genes. In some embodiments, the one or more modifications include a modification independently selected from single base substitutions, insertions, or deletions, translocations, fusions, breaks, duplications, or amplifications.

[895] In some embodiments of identifying a subject as having cancer or treating a subject having cancer (e.g., based on the presence of one or more genetic biomarkers in a first sample obtained from said subject and/or the presence of aneuploidy in a second sample obtained from the subject),

[896] In some embodiments, provided herein are methods of identifying a patient as having a cancer that include: a) determining a mutation allele frequency in a sample collected from the patient for each mutation in one or more of the following genes: NRAS, PTEN, FGFR2, KRAS, POLE, AKT1, TP53, RNF43, PPP2R1A, MAPK1, CTNNB1, PIK3CA, FBXW7, PIK3R1, APC, EGFR, BRAF, or CDKN2A; b) obtaining a score that indicates the likelihood

that the subject has a cancer by comparing the mutation allele frequency of each mutation in the selected genetic biomarkers against a reference distribution of mutation allele frequency for each mutation in control samples; and c) identifying the subject as having a cancer when the score is higher than a reference value for the score. In some embodiments, provided herein are methods of identifying a patient as having a cancer that include: a) determining a mutation allele frequency in a sample collected from the patient for each mutation in one or more of the following genes: PTEN, TP53, PIK3CA, PIK3R1, CTNNB1, KRAS, FGFR2, POLE, APC, FBXW7, RNF43, or PPP2R1A; b) obtaining a score that indicates the likelihood that the subject has a cancer by comparing the mutation allele frequency of each mutation in the selected genetic biomarkers against a reference distribution of mutation allele frequency for each mutation in control samples; and c) identifying the subject as having a cancer when the score is higher than a reference value for the score. In some embodiments, the methods further include selecting one genetic biomarker with the highest score that indicates the probability that the subject has a cancer from the two or more genetic biomarkers; and comparing the score for the selected genetic biomarker to the reference value. In some embodiments, provided herein are methods of identifying a patient as having a cancer that include: a) determining a mutation allele frequency in the sample for one or more of the genetic biomarkers; b) obtaining a score that indicates the probability that the subject does not have a cancer by comparing the mutation allele frequency of each mutation in the selected genetic biomarkers against a reference distribution of mutation allele frequency for each mutation in control samples; and c) identifying the subject as not having a cancer when the score is lower than a reference value for the score. In some embodiments, the methods further include selecting one genetic biomarker with the lowest score that indicates the probability that the subject does not have a cancer; and comparing the score for the selected genetic biomarker to the reference value. In some embodiments, the score is Stouffer's Z-score. In some embodiments, provided herein are methods of identifying a patient as having a cancer that include: a) determining a mutation allele frequency in the blood sample for two or more of the genetic biomarkers; and b) comparing the mutation allele frequency of each mutation in the selected genetic biomarkers to the maximum mutation allele frequency of each mutation for each mutation in control samples. In some

embodiments, provided herein are methods of identifying a patient as having a cancer described in the preceding paragraph, the sample is assayed in two or more test samples using a method comprising: a. assigning a unique identifier (UID) to each of a plurality of template molecules present in the sample; b. amplifying each uniquely tagged template molecule to create UID-families; and c. redundantly sequencing the amplification products. In some embodiments of identifying a patient as having a cancer, the methods further include detecting the presence of aneuploidy in the sample (e.g., the presence of aneuploidy on one or more of chromosome arms 4p, 7q, 8q, and 9q). In some embodiments of identifying a patient as having a cancer, the methods further include detecting in a circulating tumor DNA (ctDNA) sample obtained from the subject the presence of at least one genetic biomarker in one or more of the following genes: AKT1, APC, BRAF, CDKN2A, CTNNB1, EGFR, FBXW7, FGFR2, GNAS, HRAS, KRAS, NRAS, PIK3CA, PPP2R1A, PTEN, or TP53. In some embodiments, the cancer is a Stage I cancer. In some embodiments, the cancer is cervical cancer, endometrial cancer, ovarian cancer, or fallopian tubal cancer. In some embodiments, the at least one mutation comprises an inactivating modification, and wherein the at least one mutation is in a tumor suppressor gene. In some embodiments, the modifications are independently selected from single base substitutions, insertions, deletions, translocations, fusions, breaks, duplications, or amplifications. In some embodiments, the methods further include administering to the subject one or more therapeutic interventions (e.g., one or more of: surgery, adjuvant chemotherapy, neoadjuvant chemotherapy, radiation therapy, immunotherapy, targeted therapy, immune checkpoint inhibitors, or combinations thereof).

[897] In some embodiments, provided herein are methods of identifying a patient as having a cancer that include: a) determining a mutation allele frequency in a sample collected from the patient for each mutation in one or more of the following genes: TP53, PIK3CA, FGFR3, KRAS, ERBB2, CDKN2A, MLL, HRAS, MET, or VHL; b) obtaining a score that indicates the likelihood that the subject has a cancer by comparing the mutation allele frequency of each mutation in the selected genetic biomarkers against a reference distribution of mutation allele frequency for each mutation in control samples; and c) identifying the subject as having a cancer when the score is higher than a reference value for the score. In some

embodiments, the methods further include selecting one genetic biomarker with the highest score that indicates the probability that the subject has a cancer from the two or more genetic biomarkers; and comparing the score for the selected genetic biomarker to the reference value. In some embodiments, provided herein are methods of identifying a patient as having a cancer that include: a) determining a mutation allele frequency in the sample for one or more of the genetic biomarkers; b) obtaining a score that indicates the probability that the subject does not have a cancer by comparing the mutation allele frequency of each mutation in the selected genetic biomarkers against a reference distribution of mutation allele frequency for each mutation in control samples; and c) identifying the subject as not having a cancer when the score is lower than a reference value for the score. In some embodiments, the methods further include selecting one genetic biomarker with the lowest score that indicates the probability that the subject does not have a cancer; and comparing the score for the selected genetic biomarker to the reference value. In some embodiments, the score is Stouffer's Z-score. In some embodiments, provided herein are methods of identifying a patient as having a cancer that include: a) determining a mutation allele frequency in the blood sample for two or more of the genetic biomarkers; and b) comparing the mutation allele frequency of each mutation in the selected genetic biomarkers to the maximum mutation allele frequency of each mutation for each mutation in control samples. In some embodiments, provided herein are methods of identifying a patient as having a cancer described in the preceding paragraph, the sample is assayed in two or more test samples using a method comprising: a. assigning a unique identifier (UID) to each of a plurality of template molecules present in the sample; b. amplifying each uniquely tagged template molecule to create UID-families; and c. redundantly sequencing the amplification products. In some embodiments, the methods further include detecting the presence of at least one genetic biomarker (e.g., a mutation) in a TERT promoter in the sample. In some embodiments of identifying a patient as having a cancer, the methods further include detecting the presence of aneuploidy in the sample (e.g., the presence of aneuploidy on one or more of chromosome arms 5q, 8q, and 9p). In some embodiments of identifying a patient as having a cancer, the methods further include detecting in a circulating tumor DNA (ctDNA) sample obtained from the subject the presence of at least one genetic biomarker in

one or more of the following genes: AKT1, APC, BRAF, CDKN2A, CTNNB1, EGFR, FBXW7, FGFR2, GNAS, HRAS, KRAS, NRAS, PIK3CA, PPP2R1A, PTEN, or TP53. In some embodiments, the cancer is a Stage I cancer. In some embodiments, the cancer is bladder cancer or an upper-tract urothelial cancer (UTUC). In some embodiments, the at least one mutation comprises an inactivating modification, and wherein the at least one mutation is in a tumor suppressor gene. In some embodiments, the modifications are independently selected from single base substitutions, insertions, deletions, translocations, fusions, breaks, duplications, or amplifications. In some embodiments, the methods further include administering to the subject one or more therapeutic interventions (e.g., one or more of: surgery, adjuvant chemotherapy, neoadjuvant chemotherapy, radiation therapy, immunotherapy, targeted therapy, immune checkpoint inhibitors, or combinations thereof).

[898] In some embodiments, provided herein are systems for generating a report for a patient that include: at least one device configured to assay a set of genes in a biological sample to determine mutation allele frequency of each mutation in the set of genes in a sample collected from the patient, wherein the set of genes comprises one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, or 10) of the following genes: TP53, PIK3CA, FGFR3, KRAS, ERBB2, CDKN2A, MLL, HRAS, MET, and/or VHL; b) at least one computer database including: i) a first reference distribution of mutation allele frequency in control samples for each mutation in the set of genes; and ii) a second reference distribution of mutation allele frequency in samples collected from patients having a cancer for each mutation in the set of genes; c) a computer-readable program code comprising instructions to execute the following: i) inputting the mutation allele frequency in the biological sample of each mutation in the set of genes; ii) comparing the mutation allele frequency to the first reference distribution; iii) comparing the mutation allele frequency to the second reference distribution; and iv) calculating a score that indicates the likelihood that the patient has a cancer; d) a computer-readable program code comprising instructions to generate a report that indicates the patient as having a cancer if the score is higher than a reference value; or a report that indicates the patient as not having a cancer if the score is not higher than the reference value. In some embodiments of systems for generating a report for a patient, the systems further include at

least one device configured to detect the presence of at least one genetic biomarker (e.g., at least one mutation) in a TERT promoter.

[899] In some embodiments, provided herein are systems for generating a report for a patient that include: at least one device configured to assay a set of genes in a biological sample to determine mutation allele frequency of each mutation in the set of genes in a sample collected from the patient, wherein the set of genes comprises one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, or 18) of the following genes: NRAS, PTEN, FGFR2, KRAS, POLE, AKT1, TP53, RNF43, PPP2R1A, MAPK1, CTNNB1, PIK3CA, FBXW7, PIK3R1, APC, EGFR, BRAF, and/or CDKN2A; b) at least one computer database including: i) a first reference distribution of mutation allele frequency in control samples for each mutation in the set of genes; and ii) a second reference distribution of mutation allele frequency in samples collected from patients having a cancer for each mutation in the set of genes; c) a computer-readable program code comprising instructions to execute the following: i) inputting the mutation allele frequency in the biological sample of each mutation in the set of genes; ii) comparing the mutation allele frequency to the first reference distribution; iii) comparing the mutation allele frequency to the second reference distribution; and iv) calculating a score that indicates the likelihood that the patient has a cancer; d) a computer-readable program code comprising instructions to generate a report that indicates the patient as having a cancer if the score is higher than a reference value; or a report that indicates the patient as not having a cancer if the score is not higher than the reference value. In some embodiments, provided herein are systems for generating a report for a patient that include: at least one device configured to assay a set of genes in a biological sample to determine mutation allele frequency of each mutation in the set of genes in a sample collected from the patient, wherein the set of genes comprises one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, or 12) of the following genes: PTEN, TP53, PIK3CA, PIK3R1, CTNNB1, KRAS, FGFR2, POLE, APC, FBXW7, RNF43, and/or PPP2R1A; b) at least one computer database including: i) a first reference distribution of mutation allele frequency in control samples for each mutation in the set of genes; and ii) a second reference distribution of mutation allele frequency in samples collected from patients having a cancer for each mutation in the set of genes; c) a computer-readable program code comprising instructions to

execute the following: i) inputting the mutation allele frequency in the biological sample of each mutation in the set of genes; ii) comparing the mutation allele frequency to the first reference distribution; iii) comparing the mutation allele frequency to the second reference distribution; and iv) calculating a score that indicates the likelihood that the patient has a cancer; d) a computer-readable program code comprising instructions to generate a report that indicates the patient as having a cancer if the score is higher than a reference value; or a report that indicates the patient as not having a cancer if the score is not higher than the reference value. In some embodiments, provided herein are systems for generating a report for a patient that include: at least one device configured to assay a TP53 gene in a biological sample collected from the patient to determine mutation allele frequency of TP53; b) at least one computer database including: i) a first reference distribution of mutation allele frequency in control samples for TP53; and ii) a second reference distribution of mutation allele frequency in samples collected from patients having a cancer for TP53; c) a computer-readable program code comprising instructions to execute the following: i) inputting the mutation allele frequency in the biological sample of TP53; ii) comparing the mutation allele frequency to the first reference distribution; iii) comparing the mutation allele frequency to the second reference distribution; and iv) calculating a score that indicates the likelihood that the patient has a cancer; d) a computer-readable program code comprising instructions to generate a report that indicates the patient as having a cancer if the score is higher than a reference value; or a report that indicates the patient as not having a cancer if the score is not higher than the reference value.

[900] In some embodiments, provided herein are systems for generating a report to identify a cancer treatment for a patient that include: a) at least one device configured to assay a set of genes in a biological sample to determine mutation allele frequency of each mutation in the set of genes in a sample collected from the patient, wherein the set of genes comprises one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, or 10) of the following genes: TP53, PIK3CA, FGFR3, KRAS, ERBB2, CDKN2A, MLL, HRAS, MET, and/or VHL; b) at least one computer database comprising: i) a first reference distribution of mutation allele frequency in control samples for each mutation in the set of genes; ii) a second reference distribution of mutation allele frequency in samples collected from patients having a cancer for each mutation in the

set of genes; and iii) a listing of cancer treatment with efficacy linked to a biological state of at least one member of the set of genes; c) a computer-readable program code comprising instructions to execute the following: i) inputting the mutation allele frequency in the biological sample of each mutation in the set of genes; ii) comparing the mutation allele frequency to the first reference distribution; iii) comparing the mutation allele frequency to the second reference distribution; and iv) calculating a score that indicates the likelihood that the patient has a cancer; d) a computer-readable program code comprising instructions to generate a report that indicates the patient as having a cancer if the score is higher than a reference value; or a report that indicates the patient as not having a cancer if the score is not higher than the reference value; and e) a computer-readable program code comprising instructions to identify for the patient at least one cancer treatment from the listing of cancer treatments in (b)(iii) when the patient is identified as having a cancer in step (d), wherein the calculated score provides an indication that the identified cancer treatment will be effective in the patient. In some embodiments of systems for generating a report to identify a cancer treatment for a patient, the systems further include at least one device configured to detect the presence of at least one genetic biomarker (e.g., at least one mutation) in a TERT promoter.

[901] In some embodiments, provided herein are systems for generating a report to identify a cancer treatment for a patient that include: a) at least one device configured to assay a set of genes in a biological sample to determine mutation allele frequency of each mutation in the set of genes in a sample collected from the patient, wherein the set of genes comprises one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, or 18) of the following genes: NRAS, PTEN, FGFR2, KRAS, POLE, AKT1, TP53, RNF43, PPP2R1A, MAPK1, CTNNB1, PIK3CA, FBXW7, PIK3R1, APC, EGFR, BRAF, and/or CDKN2A; b) at least one computer database comprising: i) a first reference distribution of mutation allele frequency in control samples for each mutation in the set of genes; ii) a second reference distribution of mutation allele frequency in samples collected from patients having a cancer for each mutation in the set of genes; and iii) a listing of cancer treatment with efficacy linked to a biological state of at least one member of the set of genes; c) a computer-readable program code comprising instructions to execute the following: i) inputting the mutation allele frequency in the biological sample of each mutation in the set of genes; ii) comparing

the mutation allele frequency to the first reference distribution; iii) comparing the mutation allele frequency to the second reference distribution; and iv) calculating a score that indicates the likelihood that the patient has a cancer; d) a computer-readable program code comprising instructions to generate a report that indicates the patient as having a cancer if the score is higher than a reference value; or a report that indicates the patient as not having a cancer if the score is not higher than the reference value; and e) a computer-readable program code comprising instructions to identify for the patient at least one cancer treatment from the listing of cancer treatments in (b)(iii) when the patient is identified as having a cancer in step (d), wherein the calculated score provides an indication that the identified cancer treatment will be effective in the patient. In some embodiments, provided herein are systems for generating a report to identify a cancer treatment for a patient that include: a) at least one device configured to assay a set of genes in a biological sample to determine mutation allele frequency of each mutation in the set of genes comprises one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, or 12) of the following genes: PTEN, TP53, PIK3CA, PIK3R1, CTNNB1, KRAS, FGFR2, POLE, APC, FBXW7, RNF43, and/or PPP2R1A; b) at least one computer database comprising: i) a first reference distribution of mutation allele frequency in control samples for each mutation in the set of genes; ii) a second reference distribution of mutation allele frequency in samples collected from patients having a cancer for each mutation in the set of genes; and iii) a listing of cancer treatment with efficacy linked to a biological state of at least one member of the set of genes; c) a computer-readable program code comprising instructions to execute the following: i) inputting the mutation allele frequency in the biological sample of each mutation in the set of genes; ii) comparing the mutation allele frequency to the first reference distribution; iii) comparing the mutation allele frequency to the second reference distribution; and iv) calculating a score that indicates the likelihood that the patient has a cancer; d) a computer-readable program code comprising instructions to generate a report that indicates the patient as having a cancer if the score is higher than a reference value; or a report that indicates the patient as not having a cancer if the score is not higher than the reference value; and e) a computer-readable program code comprising instructions to identify for the patient at least one cancer treatment from the listing of cancer treatments in (b)(iii) when the patient is identified as having a cancer in step (d), wherein the

calculated score provides an indication that the identified cancer treatment will be effective in the patient. In some embodiments, provided herein are systems for generating a report to identify a cancer treatment for a patient that include: a) at least one device configured to assay a TP53 gene in a biological sample collected from the patient to determine mutation allele frequency of TP53; b) at least one computer database comprising: i) a first reference distribution of mutation allele frequency in control samples for TP53; ii) a second reference distribution of mutation allele frequency in samples collected from patients having a cancer for TP53; and iii) a listing of cancer treatment with efficacy linked to a biological state of TP53; c) a computer-readable program code comprising instructions to execute the following: i) inputting the mutation allele frequency in the biological sample of TP53; ii) comparing the mutation allele frequency to the first reference distribution; iii) comparing the mutation allele frequency to the second reference distribution; and iv) calculating a score that indicates the likelihood that the patient has a cancer; d) a computer-readable program code comprising instructions to generate a report that indicates the patient as having a cancer if the score is higher than a reference value; or a report that indicates the patient as not having a cancer if the score is not higher than the reference value; and e) a computer-readable program code comprising instructions to identify for the patient at least one cancer treatment from the listing of cancer treatments in (b)(iii) when the patient is identified as having a cancer in step (d), wherein the calculated score provides an indication that the identified cancer treatment will be effective in the patient.

[902] In some embodiments, provided herein are systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both that include: a) at least one device configured to assay a set of genes in a biological sample to determine mutation allele frequency of each mutation in the set of genes in a sample collected from the patient, wherein the set of genes in a sample collected from the patient, wherein the set of genes comprises one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, or 10) of the following genes: TP53, PIK3CA, FGFR3, KRAS, ERBB2, CDKN2A, MLL, HRAS, MET, and/or VHL; b) at least one computer database comprising: i) a first reference distribution of mutation allele frequency in control samples for each mutation in the set of genes; ii) a second reference distribution of mutation allele frequency in samples collected

from patients having a cancer for each mutation in the set of genes; and iii) a listing of cancer treatment with efficacy linked to a biological state of at least one member of the set of genes; c) a computer-readable program code comprising instructions to execute the following: i) inputting the mutation allele frequency in the biological sample of each mutation in the set of genes; ii) comparing the mutation allele frequency to the first reference distribution; iii) comparing the mutation allele frequency to the second reference distribution; and iv) calculating a score that indicates the likelihood that the patient has a cancer; d) a computer-readable program code comprising instructions to generate a report that indicates the patient as having a cancer if the score is higher than a reference value; or a report that indicates the patient as not having a cancer if the score is not higher than the reference value; and e) a computer-readable program code comprising instructions to identify for the patient at least one cancer treatment from the listing of cancer treatments in (b)(iii) when the patient is identified as having a cancer in step (d), wherein the calculated score provides an indication that the identified cancer treatment will be effective in the patient. In some embodiments of systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the systems further include at least one device configured to detect the presence of at least one genetic biomarker (e.g., at least one mutation) in a TERT promoter.

[903] In some embodiments, provided herein are systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both that include: a) at least one device configured to assay a set of genes in a biological sample to determine mutation allele frequency of each mutation in the set of genes in a sample collected from the patient, wherein the set of genes in a sample collected from the patient, wherein the set of genes comprises one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, or 18) of the following genes: NRAS, PTEN, FGFR2, KRAS, POLE, AKT1, TP53, RNF43, PPP2R1A, MAPK1, CTNNB1, PIK3CA, FBXW7, PIK3R1, APC, EGFR, BRAF, and/or CDKN2A; b) at least one computer database comprising: i) a first reference distribution of mutation allele frequency in control samples for each mutation in the set of genes; ii) a second reference distribution of mutation allele frequency in samples collected from patients having a cancer for each mutation in the set of genes; and iii) a listing

of cancer treatment with efficacy linked to a biological state of at least one member of the set of genes; c) a computer-readable program code comprising instructions to execute the following: i) inputting the mutation allele frequency in the biological sample of each mutation in the set of genes; ii) comparing the mutation allele frequency to the first reference distribution; iii) comparing the mutation allele frequency to the second reference distribution; and iv) calculating a score that indicates the likelihood that the patient has a cancer; d) a computer-readable program code comprising instructions to generate a report that indicates the patient as having a cancer if the score is higher than a reference value; or a report that indicates the patient as not having a cancer if the score is not higher than the reference value; and e) a computer-readable program code comprising instructions to identify for the patient at least one cancer treatment from the listing of cancer treatments in (b)(iii) when the patient is identified as having a cancer in step (d), wherein the calculated score provides an indication that the identified cancer treatment will be effective in the patient. In some embodiments, provided herein are systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both that include: a) at least one device configured to assay a set of genes in a biological sample to determine mutation allele frequency of each mutation in the set of genes comprises one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, or 12) of the following genes: PTEN, TP53, PIK3CA, PIK3R1, CTNNB1, KRAS, FGFR2, POLE, APC, FBXW7, RNF43, and/or PPP2R1A; b) at least one computer database comprising: i) a first reference distribution of mutation allele frequency in control samples for each mutation in the set of genes; ii) a second reference distribution of mutation allele frequency in samples collected from patients having a cancer for each mutation in the set of genes; and iii) a listing of cancer treatment with efficacy linked to a biological state of at least one member of the set of genes; c) a computer-readable program code comprising instructions to execute the following: i) inputting the mutation allele frequency in the biological sample of each mutation in the set of genes; ii) comparing the mutation allele frequency to the first reference distribution; iii) comparing the mutation allele frequency to the second reference distribution; and iv) calculating a score that indicates the likelihood that the patient has a cancer; d) a computer-readable program code comprising instructions to generate a report that indicates the patient

as having a cancer if the score is higher than a reference value; or a report that indicates the patient as not having a cancer if the score is not higher than the reference value; and e) a computer-readable program code comprising instructions to identify for the patient at least one cancer treatment from the listing of cancer treatments in (b)(iii) when the patient is identified as having a cancer in step (d), wherein the calculated score provides an indication that the identified cancer treatment will be effective in the patient. In some embodiments, provided herein are systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both that include: a) at least one device configured to assay a TP53 gene in a biological sample collected from the patient to determine mutation allele frequency of TP53; b) at least one computer database comprising: i) a first reference distribution of mutation allele frequency in control samples for TP53; ii) a second reference distribution of mutation allele frequency in samples collected from patients having a cancer for TP53; and iii) a listing of cancer treatment with efficacy linked to a biological state of TP53; c) a computer-readable program code comprising instructions to execute the following: i) inputting the mutation allele frequency in the biological sample of TP53; ii) comparing the mutation allele frequency to the first reference distribution; iii) comparing the mutation allele frequency to the second reference distribution; and iv) calculating a score that indicates the likelihood that the patient has a cancer; d) a computer-readable program code comprising instructions to generate a report that indicates the patient as having a cancer if the score is higher than a reference value; or a report that indicates the patient as not having a cancer if the score is not higher than the reference value; and e) a computer-readable program code comprising instructions to identify for the patient at least one cancer treatment from the listing of cancer treatments in (b)(iii) when the patient is identified as having a cancer in step (d), wherein the calculated score provides an indication that the identified cancer treatment will be effective in the patient.

[904] In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the systems further include a computer-readable program code comprising instructions to execute the following: i) determining a mutation allele frequency

in the sample for two or more of the genetic biomarkers; ii) obtaining a score that indicates the likelihood that the subject has a cancer by comparing the mutation allele frequency of each mutation in the selected genetic biomarkers against a reference distribution of mutation allele frequency for each mutation in control samples; and ii) identifying the subject as having a cancer when the score is higher than a reference value for the score. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the systems further include a computer-readable program code comprising instructions to execute the following instructions: i) selecting one genetic biomarker with the highest score that indicates the probability that the subject has a cancer from the two or more genetic biomarkers; and ii) comparing the score for the selected genetic biomarker to the reference value. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the score is Stouffer's Z-score. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the systems further include a computer-readable program code comprising instructions to execute the following instructions: i) determining a mutation allele frequency in the sample for two or more of the genetic biomarkers; and ii) comparing the mutation allele frequency of each mutation in the selected genetic biomarkers to the maximum mutation allele frequency of each mutation for each mutation in control samples.

[905] In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the device configured to assay a set of genes comprises a device that employs a includes a PCR-based multiplex assay, using a PCR-based singleplex assay, a digital PCR assay, a droplet digital PCR (ddPCR) assay, a microarray assay, a next-

generation sequencing assay, a Sanger sequencing assay, a quantitative PCR assay, or a ligation assay. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the multiplex PCR-based sequencing assay comprises: a. assigning a unique identifier (UID) to each of a plurality of template molecules present in the sample; b. amplifying each uniquely tagged template molecule to create UID-families; and c. redundantly sequencing the amplification products. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the system further includes a device configured to detect the presence of aneuploidy in a biological sample. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both that include at least one device configured to assay one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 16, or 16) of the following genes: NRAS, CTNNB1, PIK3CA, FBXW7, APC, EGFR, BRAF, CDKN2A, PTEN, FGFR2, HRAS, KRAS, AKT1, TP53, PPP2R1A, and/or GNAS, the system further includes a device (e.g., a device that includes a multiplex immunoassay system) configured to detect the presence of aneuploidy in a biological sample. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both that include: 1) at least one device configured to assay one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 16, or 16) of the following genes: NRAS, CTNNB1, PIK3CA, FBXW7, APC, EGFR, BRAF, CDKN2A, PTEN, FGFR2, HRAS, KRAS, AKT1, TP53, PPP2R1A, and/or GNAS, and 2) at least one device configured to detect the presence of a genetic biomarker (e.g., at least one mutation) in a TERT promoter, the system further includes a device (e.g., a device that includes a multiplex immunoassay system) configured to detect the presence of aneuploidy in a

biological sample. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both that include at least one device configured to assay one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, or 18) of the following genes: NRAS, PTEN, FGFR2, KRAS, POLE, AKT1, TP53, RNF43, PPP2R1A, MAPK1, CTNNB1, PIK3CA, FBXW7, PIK3R1, APC, EGFR, BRAF, and/or CDKN2A, the system further includes a device (e.g., a device that includes a multiplex immunoassay system) configured to detect the presence of aneuploidy in a biological sample. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both that include at least one device configured to assay one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, or 12) of the following genes: PTEN, TP53, PIK3CA, PIK3R1, CTNNB1, KRAS, FGFR2, POLE, APC, FBXW7, RNF43, and/or PPP2R1A, the system further includes a device (e.g., a device that includes a multiplex immunoassay system) configured to detect the presence of aneuploidy in a biological sample. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both that include at least one device configured to assay TP53, the system further includes a device (e.g., a device that includes a multiplex immunoassay system) configured to detect the presence of aneuploidy in a biological sample. The presence of aneuploidy can be detected on one or more chromosomes or chromosomal arms that are associated with cancer. In some embodiments, the presence of aneuploidy is detected on one or more of chromosomal arms 5q, 8q, and/or 9p. In some embodiments, the presence of aneuploidy is detected on one or more of chromosomal arms 4p, 7q, 8q, and/or 9q

[906] In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further

diagnostic testing, or both, the sensitivity of the system in identifying a subject as having cancer is improved as compared to conventional systems for generating a report for a patient. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the specificity of the system in identifying a subject as having cancer is improved as compared to conventional systems for generating a report for a patient. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the first and second reference distribution of mutation allele frequency values are input into the system from a location that is remote from the at least one computer database. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, first and second reference distribution of mutation allele frequency values are input into the system over an internet connection. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the report is in electronic or paper format.

[907] In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both, the cancer is any of the variety of cancer types described herein (see, e.g., section entitled "Cancers"). In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both that include at least one device configured to assay comprises one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, or 10) of the

following genes: TP53, PIK3CA, FGFR3, KRAS, ERBB2, CDKN2A, MLL, HRAS, MET, and/or VHL and at least one a device configured to detect the presence of aneuploidy in a biological sample, the cancer is bladder cancer or an upper-tract urothelial carcinoma. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both that include at least one device configured to assay one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, or 18) of the following genes: NRAS, PTEN, FGFR2, KRAS, POLE, AKT1, TP53, RNF43, PPP2R1A, MAPK1, CTNNB1, PIK3CA, FBXW7, PIK3R1, APC, EGFR, BRAF, and/or CDKN2A and at least one a device configured to detect the presence of aneuploidy in a biological sample, the cancer is cervical cancer, endometrial cancer, ovarian cancer, or fallopian tubal cancer. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both that include at least one device configured to assay one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, or 12) of the following genes: PTEN, TP53, PIK3CA, PIK3R1, CTNNB1, KRAS, FGFR2, POLE, APC, FBXW7, RNF43, and/or PPP2R1A and at least one a device configured to detect the presence of aneuploidy in a biological sample, the cancer is endometrial cancer. In some embodiments of systems for generating a report for a patient, systems for generating a report to identify a cancer treatment for a patient, or systems for generating a report for a patient to identify the patient as a candidate for increased monitoring, further diagnostic testing, or both that include at least one device configured to assay TP53 and at least one a device configured to detect the presence of aneuploidy in a biological sample, the cancer is a high-grade serous carcinoma. In some embodiments of systems for generating a report for a patient or systems for generating a report to identify a cancer treatment for a patient, the patient is identified as a candidate for increased monitoring, further diagnostic testing, or both (e.g. any of the variety of increased monitoring or further diagnostic methods described herein).

[908] Many of the currently approved tests for earlier cancer detection are procedural in nature, and include colonoscopy, mammography, and cervical cytology analysis. To date, the vast majority of cancer patients evaluated with mutation-based liquid biopsies have advanced stage disease. Yet another issue with liquid biopsies is the identification of the underlying organ of origin. Because the same gene mutations drive multiple tumor types, liquid biopsies based on such alterations cannot generally identify the location of the primary tumor giving rise to a positive blood test. Described herein is a non-invasive combinatorial blood test (e.g., a test that combines DNA markers and protein markers) for the early detection and localization of many common cancers.

[909] This document provides methods and materials for assessing and/or treating mammals (e.g., humans) having, or suspected of having, cancer. In some embodiments, this document provides methods and materials for identifying a mammal as having cancer. For example, a sample (e.g., a blood sample) obtained from a mammal can be assessed to determine if the mammal has cancer based, at least in part, on the presence or absence of one or more biomarkers (e.g., genetic biomarkers) and/or an elevated level of one or more biomarkers (e.g., peptide biomarkers). In some embodiments, this document provides methods and materials for identifying the location (e.g., the anatomic site) of a cancer in a mammal. For example, a sample (e.g., a blood sample) obtained from a mammal can be assessed to determine the location of the cancer in the mammal based, at least in part, on the presence or absence of one or more biomarkers (e.g., genetic biomarkers) and/or an elevated level of one or more biomarkers (e.g., peptide biomarkers). In some embodiments, this document provides methods and materials for identifying a mammal as having cancer, and administering one or more pharmacological interventions to treat the mammal. For example, a sample (e.g., a blood sample) obtained from a mammal can be assessed to determine if the mammal has cancer based, at least in part, on the presence or absence of one or more biomarkers (e.g., genetic biomarkers) and/or an elevated level of one or more biomarkers (e.g., peptide biomarkers), and administering one or more cancer treatments to the mammal.

[910] As demonstrated herein, an analysis of only 2,001 bp of genomic DNA could detect at least one mutation in 82% of eight common cancer types. A test (CancerSEEK) was

designed which assessed the levels of 10 circulating proteins as well as mutations of these 2,001 bp in circulating cell-free DNA. This test was applied to 1,005 patients with cancers of the liver, ovary, esophagus, stomach, pancreas, colorectum, lung, or breast. CancerSEEK tests were positive in a median of 70% of the eight cancer types, while fewer than 1% of 812 normal individuals scored positively. The sensitivities ranged from 69% to 98% for the detection of five cancer types (liver, ovary, esophagus, stomach, and pancreas) for which there are no screening tests available for average-risk individuals. Moreover, the source of the cancer could be localized to a small number of anatomic sites in a median of 84% of the patients scoring positive in the CancerSEEK assay.

[911] Having the ability to use a blood test having very high specificity (e.g., by combining DNA markers and protein markers) can allow clinicians to detect cancers at earlier stages resulting in earlier treatment with fewer unnecessary follow-up procedures, less anxiety, and/or reduced cancer deaths.

[912] In general, one aspect of this document features a method for identifying a mammal as having cancer. The method can include, or consist essentially of, detecting one or more genetic biomarkers in circulating DNA in a blood sample obtained from a mammal; detecting an elevated level of one or more peptide biomarkers in the blood sample obtained from a mammal; and identifying the mammal as having cancer when the presence of one or more genetic biomarkers is detected in circulating DNA in said blood sample, when an elevated level of one or more peptide biomarkers is detected in said blood sample, or both. The mammal can be a human. The blood sample can be a plasma sample. The cancer can be a Stage I cancer. The cancer can be a liver cancer, an ovary cancer, an esophageal cancer, a stomach cancer, a pancreatic cancer, a colorectal cancer, a lung cancer, a breast cancer, or a prostate cancer. The one or more genetic biomarkers can include one or more modifications in one or more genes. The one or more modifications can include inactivating modifications, and the one or more genes can include tumor suppressor genes. The one or more modifications can independently be selected from single base substitutions, insertions, and deletions. The one or more genes are can include NRAS, CTNNB1, PIK3CA, FBXW7, APC, EGFR, BRAF, CDKN2A, PTEN, FGFR2, HRAS, KRAS, AKT1, TP53, PPP2R1A,

and/or GNAS. The one or more modifications can independently be selected from the modifications set forth in Table 5. The step of detecting the presence of one or more genetic biomarkers can be performed using a multiplex PCR-based sequencing assay. The multiplex PCR-based sequencing assay can include assigning a unique identifier (UID) to each template molecule; amplifying each uniquely tagged template molecule to create UID-families; and redundantly sequencing the amplification products. The one or more peptide biomarkers can include prolactin, OPN, IL-6, CEA, CA125, HGF, Myeloperoxidase, CA19-9, Midkine, and/or TIMP-1. The step of detecting the level of one or more peptide biomarkers can be performed using a multiplex immunoassay system. The method also can include identifying a location of said cancer. The method also can include administering to the mammal one or more cancer treatments. The one or more cancer treatments can include surgery, chemotherapy, hormone therapy, targeted therapy, radiation therapy, and combinations thereof.

[913] In another aspect, this document features a method for treating a mammal having cancer. The method can include, or consist essentially of, detecting one or more genetic biomarkers in circulating DNA in a blood sample obtained from a mammal; detecting an elevated level of one or more peptide biomarkers in the blood sample obtained from a mammal; and administering one or more cancer treatments to said mammal when the presence of one or more genetic biomarkers is detected in circulating DNA in said blood sample, when an elevated level of one or more peptide biomarkers is detected in said blood sample, or both. The one or more cancer treatments can include surgery, chemotherapy, hormone therapy, targeted therapy, radiation therapy, and combinations thereof. The mammal can be a human. The blood sample can be a plasma sample. The cancer can be a Stage I cancer. The cancer can be a liver cancer, an ovary cancer, an esophageal cancer, a stomach cancer, a pancreatic cancer, a colorectal cancer, a lung cancer, a breast cancer, or a prostate cancer. The one or more genetic biomarkers can include one or more modifications in one or more genes. The one or more modifications can include inactivating modifications, and the one or more genes can include tumor suppressor genes. The one or more modifications can independently be selected from single base substitutions, insertions, and deletions. The one or more genes are can include NRAS, CTNNB1, PIK3CA, FBXW7,

APC, EGFR, BRAF, CDKN2A, PTEN, FGFR2, HRAS, KRAS, AKT1, TP53, PPP2R1A, and/or GNAS. The one or more modifications can independently be selected from the modifications set forth in Table 5. The step of detecting the presence of one or more genetic biomarkers can be performed using a multiplex PCR-based sequencing assay. The multiplex PCR-based sequencing assay can include assigning a unique identifier (UID) to each template molecule; amplifying each uniquely tagged template molecule to create UID-families; and redundantly sequencing the amplification products. The one or more peptide biomarkers can include prolactin, OPN, IL-6, CEA, CA125, HGF, Myeloperoxidase, CA19-9, Midkine, and/or TIMP-1. The step of detecting the level of one or more peptide biomarkers can be performed using a multiplex immunoassay system.

[914] In another aspect, this document features a method for identifying the location of a cancer in a mammal. The method can include, or consist essentially of, detecting one or more genetic biomarkers in circulating DNA in a blood sample obtained from a mammal; detecting an elevated level of one or more peptide biomarkers in the blood sample obtained from a mammal; and identifying the location of the cancer in the mammal when the presence of one or more genetic biomarkers is detected in circulating DNA in said blood sample, when an elevated level of one or more peptide biomarkers is detected in said blood sample, or both. The mammal can be a human. The blood sample can be a plasma sample. The cancer can be a Stage I cancer. The cancer can be a liver cancer, an ovary cancer, an esophageal cancer, a stomach cancer, a pancreatic cancer, a colorectal cancer, a lung cancer, a breast cancer, or a prostate cancer. The one or more genetic biomarkers can include one or more modifications in one or more genes. The one or more modifications can include inactivating modifications, and the one or more genes can include tumor suppressor genes. The one or more modifications can independently be selected from single base substitutions, insertions, and deletions. The one or more genes are can include NRAS, CTNNB1, PIK3CA, FBXW7, APC, EGFR, BRAF, CDKN2A, PTEN, FGFR2, HRAS, KRAS, AKT1, TP53, PPP2R1A, and/or GNAS. The one or more modifications can independently be selected from the modifications set forth in Table 5. The step of detecting the presence of one or more genetic biomarkers can be performed using a multiplex PCR-based sequencing assay. The multiplex PCR-based sequencing assay can include assigning a unique identifier (UID) to each

template molecule; amplifying each uniquely tagged template molecule to create UID-families; and redundantly sequencing the amplification products. The one or more peptide biomarkers can include prolactin, OPN, IL-6, CEA, CA125, HGF, Myeloperoxidase, CA19-9, Midkine, and/or TIMP-1. The step of detecting the level of one or more peptide biomarkers can be performed using a multiplex immunoassay system.

[915] Provided herein are methods for identifying the presence of a cancer in a human subject comprising: detecting in a first biological sample isolated from the human subject the presence of one or more genetic alterations in cell-free DNA derived from a gene selected from the group consisting of: AKT1, APC, BRAF, CDKN2, CTNNB1, FBXW7, FGFR2, GNAS, HRAS, KRAS, PPP2R1A, TP53, PTEN, PIK3CA, EGFR and NRAS, and combinations thereof; detecting a level of one or more protein biomarkers in a second biological sample isolated from the human subject, wherein the protein biomarker is selected from the group consisting of: carbohydrate antigen 19-9 (CA19-9), carcinoembryonic antigen (CEA), hepatocyte growth factor (HGF), osteopontin (OPN), CA125, AFP, prolactin, TIMP-1, follistatin, G-CSF, and CA15-3, and combinations thereof; comparing the detected levels of the one or more protein biomarkers to one or more reference levels of the protein biomarkers; and identifying the presence of the cancer in the human subject when the presence of one or more genetic alterations in the cell-free DNA is detected, the detected levels of the one or more protein biomarkers are higher than the reference levels of the one or more protein biomarkers, or both. In some embodiments, the first biological sample comprises blood, plasma, urine, cerebrospinal fluid, saliva, sputum, broncho-alveolar lavage, bile, lymphatic fluid, cyst fluid, stool, ascites, and combinations thereof. In some embodiments, the first biological sample, the second biological sample, or both comprises plasma. In some embodiments, the first and second biological samples are the same.

[916] In some embodiments of identifying the presence of a cancer in a human subject, the step of detecting the presence of one or more genetic alterations in cell-free DNA in the first biological sample comprises amplifying an amplicon comprising codons and their surrounding splice sites, wherein the codons are selected from the group consisting of: codons 16-18 of AKT1; codons 1304-1311 or 1450-1459 of APC; codons 591-602 of BRAF;

codons 51-58 or 76-88 of CDKN2A; codons 31-39 or 38-47 of CTNNB1; codons 856-868 of EGFR; codons 361-371, 464-473, 473-483, or 498-507 of FBXW7; codons 250-256 of FGFR2; codons 199-208 of GNAS; codons 7-19 of HRAS; codons 7-14, 57-65, or 143-148 of KRAS; codons 3-15 or 54-63 of NRAS; codons 80-90, 343-348, 541-551, or 1038-1050 of PIK3CA; codons 175-187 of PPP2R1A; codons 90-98, 125-132, 133-146, 145-154 of PTEN; codons 10-22, 25-32, 33-40, 40-52, 52-64, 82-94, 97-110, 112-125, 123-125, 126-132, 132-142, 150-163, 167-177, 175-186, 187-195, 195-206, 207-219, 219-224, 226-237, 232-245, 248-261, 261-268, 272-283, 279-290, 298-307, 307-314, 323-331, 333-344, 344-355, 367-375, or 374-386 of TP53, and combinations thereof. In some embodiments, the step of detecting the presence of one or more genetic alterations in cell-free DNA in the first biological sample comprises sequencing gene regions comprising codons and their surrounding splice sites, wherein the codons are selected from the group consisting of: codons 16-18 of AKT1; codons 1304-1311 or 1450-1459 of APC; codons 591-602 of BRAF; codons 51-58 or 76-88 of CDKN2A; codons 31-39 or 38-47 of CTNNB1; codons 856-868 of EGFR; codons 361-371, 464-473, 473-483, or 498-507 of FBXW7; codons 250-256 of FGFR2; codons 199-208 of GNAS; codons 7-19 of HRAS; codons 7-14, 57-65, or 143-148 of KRAS; codons 3-15 or 54-63 of NRAS; codons 80-90, 343-348, 541-551, or 1038-1050 of PIK3CA; codons 175-187 of PPP2R1A; codons 90-98, 125-132, 133-146, 145-154 of PTEN; codons 10-22, 25-32, 33-40, 40-52, 52-64, 82-94, 97-110, 112-125, 123-125, 126-132, 132-142, 150-163, 167-177, 175-186, 187-195, 195-206, 207-219, 219-224, 226-237, 232-245, 248-261, 261-268, 272-283, 279-290, 298-307, 307-314, 323-331, 333-344, 344-355, 367-375, or 374-386 of TP53, and combinations thereof. In some embodiments, the step of detecting the presence of one or more genetic alterations in cell-free DNA in the first biological sample comprises sequencing gene regions comprising codons and their surrounding splice from each of: codons 16-18 of AKT1; codons 1304-1311 and 1450-1459 of APC; codons 591-602 of BRAF; codons 51-58 and 76-88 of CDKN2A; codons 31-39 and 38-47 of CTNNB1; codons 856-868 of EGFR; codons 361-371, 464-473, 473-483, and 498-507 of FBXW7; codons 250-256 of FGFR2; codons 199-208 of GNAS; codons 7-19 of HRAS; codons 7-14, 57-65, and 143-148 of KRAS; codons 3-15 and 54-63 of NRAS; codons 80-90, 343-348, 541-551, and 1038-1050 of PIK3CA; codons 175-187 of PPP2R1A;

codons 90-98, 125-132, 133-146, 145-154 of PTEN; codons 10-22, 25-32, 33-40, 40-52, 52-64, 82-94, 97-110, 112-125, 123-125, 126-132, 132-142, 150-163, 167-177, 175-186, 187-195, 195-206, 207-219, 219-224, 226-237, 232-245, 248-261, 261-268, 272-283, 279-290, 298-307, 307-314, 323-331, 333-344, 344-355, 367-375, and 374-386 of TP53, and combinations thereof.

[917] In some embodiments of identifying the presence of a cancer in a human subject, the one or more protein biomarkers include CA19-9. In some embodiments, the reference level of the CA19-9 protein biomarker is 92 U/mL. In some embodiments, the one or more protein biomarkers include CEA. In some embodiments, the reference level of the CEA protein biomarker is 7.5 ng/mL. In some embodiments, the one or more protein biomarkers include HGF. In some embodiments, the reference level of the HGF protein biomarker is 0.89 ng/mL. In some embodiments, the one or more protein biomarkers include OPN. In some embodiments, the reference level of the OPN protein biomarker is 158 ng/mL. In some embodiments, the one or more protein biomarkers include CA125. In some embodiments, the reference level of the CA125 protein biomarker is 577 U/mL. In some embodiments, the one or more protein biomarkers include AFP. In some embodiments, the reference level of the AFP protein biomarker is 21 ng/mL. In some embodiments, the one or more protein biomarkers include prolactin. In some embodiments, the reference level of the prolactin protein biomarker is 145 ng/mL. In some embodiments, the one or more protein biomarkers include TIMP-1. In some embodiments, the reference level of the TIMP-1 protein biomarker is 177ng/mL. In some embodiments, the one or more protein biomarkers include follistatin. In some embodiments, the reference level of the follistatin protein biomarker is 2 ng/mL In some embodiments, the one or more protein biomarkers include G-CSF. In some embodiments, the reference level of the G-CSF protein biomarker is 800 pg/mL. In some embodiments, the one or more protein biomarkers include CA15-3. In some embodiments, the reference level of the CA15-3 protein biomarker is 98 U/mL.

[918] In some embodiments of identifying the presence of a cancer in a human subject, the presence of the cancer in the human subject is identified when: (i) the presence of one or more genetic alterations in cell-free DNA derived is detected, and (ii) the detected levels of

the one or more protein biomarkers are higher than the reference levels of the one or more protein biomarkers.

[919] In some embodiments of identifying the presence of a cancer in a human subject, the presence of one or more genetic alterations in cell-free DNA in the first biological sample is detected by amplifying the cell-free DNA to form families of amplicons in which each member of a family is derived from a single template molecule in the cell-free DNA, wherein each member of a family is marked by a common oligonucleotide barcode, and wherein each family is marked by a distinct oligonucleotide barcode. In some embodiments, the oligonucleotide barcode is introduced into the template molecule by a step of amplifying with a population of primers which collectively contain a plurality of oligonucleotide barcodes. In some embodiments, the oligonucleotide barcode is endogenous to the template molecule, and an adapter comprising a DNA synthesis priming site is ligated to an end of the template molecule adjacent to the oligonucleotide barcode.

[920] In some embodiments of identifying the presence of a cancer in a human subject, a therapeutic intervention is administered to the subject when the presence of cancer is identified. In some embodiments, the therapeutic intervention is selected from the group consisting of: adoptive T cell therapy, radiation therapy, surgery, administration of a chemotherapeutic agent, administration of an immune checkpoint inhibitor, administration of a targeted therapy, administration of a kinase inhibitor, administration of a signal transduction inhibitor, administration of a bispecific antibody, administration of a monoclonal antibody, and combinations thereof. In some embodiments, cancer, and wherein the therapeutic intervention is more effective than if the therapeutic intervention were to be administered to a human subject at a later time.

[921] In some embodiments of identifying the presence of a cancer in a human subject, the presence of cancer in the human subject is detected at a time prior to diagnosis of the human subject with cancer. In some embodiments, the presence of cancer in the human subject is detected at a time prior to the human subject exhibiting symptoms associated with cancer.

[922] In some embodiments of identifying the presence of a cancer in a human subject, the human subject is human subjected to a radiologic scanning of an organ or body region to

identify the location of the cancer. In some embodiments, the human subject is human subjected to whole body radiologic scanning to identify the location of the cancer. In some embodiments, the scanning is a Positron emission tomography-computed tomography (PET-CT) scan.

[923] In some embodiments, the cancer is selected from the group consisting of: pancreatic cancer, colon cancer, esophageal cancer, stomach cancer, ovarian cancer, liver cancer, lung cancer, and breast cancer, and combinations thereof.

[924] Also provided herein are methods for identifying the presence of cancer in a human subject comprising: detecting a level of one or more protein biomarkers in a first biological sample isolated from the human subject, wherein the one or more protein biomarkers are selected from the group consisting of: carbohydrate antigen 19-9 (CA19-9), carcinoembryonic antigen (CEA), hepatocyte growth factor (HGF), osteopontin (OPN), CA125, AFP, prolactin, TIMP-1, follistatin, G-CSF, and CA15-3, and combinations thereof; comparing the detected levels of the one or more protein biomarkers to one or more reference levels of the protein biomarkers; and identifying the presence of cancer in the human subject when the detected levels of the one or more protein biomarkers are higher than the reference levels of the one or more protein biomarkers.

[925] Provided herein are methods for identifying the presence of pancreatic cancer in a human subject comprising: detecting in a first biological sample isolated from the human subject the presence of one or more genetic alterations in cell-free DNA derived from a gene selected from the group consisting of: KRAS, TP53, CDKN2A, SMAD4, and combinations thereof; detecting a level of one or more protein biomarkers in a second biological sample isolated from the human subject, wherein the one or more protein biomarkers are selected from the group consisting of: carbohydrate antigen 19-9 (CA19-9), carcinoembryonic antigen (CEA), hepatocyte growth factor (HGF), osteopontin (OPN), and combinations thereof; comparing the detected levels of the one or more protein biomarker to one or more reference levels of the protein biomarkers; and identifying the presence of pancreatic cancer in the human subject when the presence of one or more genetic alterations in the cell-free DNA is detected, the detected levels of the one or more protein biomarkers are higher than the

reference levels of the one or more protein biomarkers, or both. In some embodiments, the first biological sample comprises blood, plasma, urine, cerebrospinal fluid, saliva, sputum, broncho-alveolar lavage, bile, lymphatic fluid, cyst fluid, stool, ascites, and combinations thereof. In some embodiments, the first biological sample, the second biological sample, or both comprises plasma. In some embodiments, the first and second biological samples are the same.

[926] In some embodiments of methods for identifying the presence of pancreatic cancer in a human subject, the one or more genetic alterations occur in codons 12 or 61 of the KRAS gene. In some embodiments, the one or more protein biomarkers include CA19-9. In some embodiments, the reference level of the CA19-9 protein biomarker is 100 U/mL. In some embodiments, the one or more protein biomarkers include CEA. In some embodiments, the reference level of the CEA protein biomarker is 7.5 ng/mL. In some embodiments, the one or more protein biomarkers include HGF. In some embodiments, the reference level of the HGF protein biomarker is 0.92 ng/mL. In some embodiments, the one or more protein biomarkers include OPN. In some embodiments, the reference level of the OPN protein biomarker is 158 ng/mL. In some embodiments, detecting the level of the one or more protein biomarkers comprises detecting the levels of each of CA19-9, CEA, HGF, and OPN; and comparing the detected levels of the one or more protein biomarkers to one or more reference levels of the protein biomarker comprises comparing the detected levels of each of CA19-9, CEA, HGF, and OPN to a reference level of each of CA19-9, CEA, HGF, and OPN.

[927] [09] In some embodiments of methods for identifying the presence of pancreatic cancer in a human subject, the presence of pancreatic cancer in the human subject is identified when: (i) the presence of one or more genetic alterations in cell-free DNA derived from the KRAS gene are detected, and (ii) the detected levels of the one or more protein biomarkers are higher than the reference levels of the one or more protein biomarkers. In some embodiments of methods for identifying the presence of pancreatic cancer in a human subject, the one or more genetic alterations are detected by amplifying the cell-free DNA to form families of amplicons in which each member of a family is derived from a single template molecule in the cell-free DNA, wherein each member of a family is marked by a

common oligonucleotide barcode, and wherein each family is marked by a distinct oligonucleotide barcode. In some embodiments, the oligonucleotide barcode is introduced into the template molecule by a step of amplifying with a population of primers which collectively contain a plurality of oligonucleotide barcodes. In some embodiments, the oligonucleotide barcode is endogenous to the template molecule, and an adapter comprising a DNA synthesis priming site is ligated to an end of the template molecule adjacent to the oligonucleotide barcode.

[928] In some embodiments, a therapeutic intervention to the human subject when the presence of pancreatic cancer is identified. In some embodiments, the therapeutic intervention is selected from the group consisting of: adoptive T cell therapy, radiation therapy, surgery, administration of a chemotherapeutic agent, administration of an immune checkpoint inhibitor, administration of a targeted therapy, administration of a kinase inhibitor, administration of a signal transduction inhibitor, administration of a bispecific antibody, administration of a monoclonal antibody, and combinations thereof. In some embodiments, the therapeutic intervention is administered at a time when the human subject has an early-stage pancreatic cancer, and wherein the therapeutic intervention is more effective than if the therapeutic intervention were to be administered to a human subject at a later time.

[929] In some embodiments, the presence of pancreatic cancer in the human subject is detected at a time prior to diagnosis of the human subject with pancreatic cancer. In some embodiments, the presence of pancreatic cancer in the human subject is detected at a time prior to the human subject exhibiting symptoms associated with pancreatic cancer.

[930] Also provided herein are methods for identifying the presence of pancreatic cancer in a human subject comprising: detecting a level of one or more protein biomarkers in a first biological sample isolated from the human subject, wherein the one or more protein biomarkers are selected from the group consisting of: carbohydrate antigen 19-9 (CA19-9), carcinoembryonic antigen (CEA), hepatocyte growth factor (HGF), osteopontin (OPN), and combinations thereof; comparing the detected levels of the one or more protein biomarker to one or more reference levels of the protein biomarkers; and identifying the presence of

pancreatic cancer in the human subject when the detected levels of the one or more protein biomarkers are higher than the reference levels of the one or more protein biomarkers.

[931] Provided herein are methods for identifying the presence of a cancer in a human subject comprising: detecting in a first biological sample isolated from the subject the presence of one or more genetic alterations in cell-free DNA derived from a gene selected from the group consisting of: AKT1, APC, BRAF, CDKN2, CTNNB1, FBXW7, FGFR2, GNAS, HRAS, KRAS, PPP2R1A, TP53, PTEN, PIK3CA, EGFR and NRAS, and combinations thereof; detecting in a second biological sample isolated from the subject the absence of one or more genetic alterations in DNA derived from a gene selected from the group consisting of: AKT1, APC, BRAF, CDKN2, CTNNB1, FBXW7, FGFR2, GNAS, HRAS, KRAS, PPP2R1A, TP53, PTEN, PIK3CA, EGFR and NRAS, and combinations thereof, wherein the second biological sample is isolated from white blood cells of the subject; identifying the presence of the cancer in the subject when the one or more genetic alterations that are detected in the first sample are not detected in the second sample. In some embodiments, the first biological sample, the second biological sample, or both comprise blood, plasma, urine, cerebrospinal fluid, saliva, sputum, broncho-alveolar lavage, bile, lymphatic fluid, cyst fluid, stool, ascites, and combinations thereof. In some embodiments, the first biological sample, the second biological sample, or both comprises plasma. In some embodiments, the first and second biological samples are the same. In some embodiments of identifying the presence of a cancer in a human subject, the methods further comprise detecting a level of one or more protein biomarkers in a third biological sample isolated from the subject, wherein the protein biomarker is selected from the group consisting of: carbohydrate antigen 19-9 (CA19-9), carcinoembryonic antigen (CEA), hepatocyte growth factor (HGF), osteopontin (OPN), CA125, AFP, prolactin, TIMP-1, follistatin, G-CSF, and CA15-3 and combinations thereof; comparing the detected levels of the one or more protein biomarkers to one or more reference levels of the protein biomarkers; and identifying the presence of the cancer in the subject when the presence of one or more genetic alterations in the cell-free DNA is detected in the first sample, the absence of one or more genetic alterations is detected in DNA from the second sample, and the detected levels of the one or more protein biomarkers are higher than the reference levels of the one or more

protein biomarkers. In some embodiments, the third biological sample is the same as the first biological sample.

[932] In some embodiments of identifying the presence of a cancer in a human subject, the step of detecting the presence of one or more genetic alterations in cell-free DNA in the first biological sample, the step of detecting the absence of one or more genetic alterations in DNA in the second biological sample, or both comprises amplifying an amplicon comprising codons and their surrounding splice sites, wherein the codons are selected from the group consisting of: codons 16-18 of AKT1; codons 1304-1311 or 1450-1459 of APC; codons 591-602 of BRAF; codons 51-58 or 76-88 of CDKN2A; codons 31-39 or 38-47 of CTNNB1; codons 856-868 of EGFR; codons 361-371, 464-473, 473-483, or 498-507 of FBXW7; codons 250-256 of FGFR2; codons 199-208 of GNAS; codons 7-19 of HRAS; codons 7-14, 57-65, or 143-148 of KRAS; codons 3-15 or 54-63 of NRAS; codons 80-90, 343-348, 541-551, or 1038-1050 of PIK3CA; codons 175-187 of PPP2R1A; and codons 90-98, 125-132, 133-146, 145-154 of PTEN; and codons 10-22, 25-32, 33-40, 40-52, 52-64, 82-94, 97-110, 112-125, 123-125, 126-132, 132-142, 150-163, 167-177, 175-186, 187-195, 195-206, 207-219, 219-224, 226-237, 232-245, 248-261, 261-268, 272-283, 279-290, 298-307, 307-314, 323-331, 333-344, 344-355, 367-375, or 374-386 of TP53. In some embodiments, the step of detecting the presence of one or more genetic alterations in cell-free DNA in the first biological sample, the step of detecting the absence of one or more genetic alterations in DNA in the second biological sample, or both comprises sequencing gene regions comprising codons and their surrounding splice sites, wherein the codons are selected from the group consisting of: codons 16-18 of AKT1; codons 1304-1311 or 1450-1459 of APC; codons 591-602 of BRAF; codons 51-58 or 76-88 of CDKN2A; codons 31-39 or 38-47 of CTNNB1; codons 856-868 of EGFR; codons 361-371, 464-473, 473-483, or 498-507 of FBXW7; codons 250-256 of FGFR2; codons 199-208 of GNAS; codons 7-19 of HRAS; codons 7-14, 57-65, or 143-148 of KRAS; codons 3-15 or 54-63 of NRAS; codons 80-90, 343-348, 541-551, or 1038-1050 of PIK3CA; codons 175-187 of PPP2R1A; and codons 90-98, 125-132, 133-146, 145-154 of PTEN; and codons 10-22, 25-32, 33-40, 40-52, 52-64, 82-94, 97-110, 112-125, 123-125, 126-132, 132-142, 150-163, 167-177, 175-186, 187-195, 195-206, 207-219, 219-224, 226-237, 232-245, 248-261, 261-268, 272-283, 279-290, 298-307,

307-314, 323-331, 333-344, 344-355, 367-375, or 374-386 of TP53. In some embodiments, the step of detecting the presence of one or more genetic alterations in cell-free DNA in the first biological sample, the step of detecting the absence of one or more genetic alterations in DNA in the second biological sample, or both comprises sequencing gene regions comprising codons and their surrounding splice from each of: codons 16-18 of AKT1; codons 1304-1311 and 1450-1459 of APC; codons 591-602 of BRAF; codons 51-58 and 76-88 of CDKN2A; codons 31-39 and 38-47 of CTNNB1; codons 856-868 of EGFR; codons 361-371, 464-473, 473-483, and 498-507 of FBXW7; codons 250-256 of FGFR2; codons 199-208 of GNAS; codons 7-19 of HRAS; codons 7-14, 57-65, and 143-148 of KRAS; codons 3-15 and 54-63 of NRAS; codons 80-90, 343-348, 541-551, and 1038-1050 of PIK3CA; codons 175-187 of PPP2R1A; and codons 90-98, 125-132, 133-146, 145-154 of PTEN; and codons 10-22, 25-32, 33-40, 40-52, 52-64, 82-94, 97-110, 112-125, 123-125, 126-132, 132-142, 150-163, 167-177, 175-186, 187-195, 195-206, 207-219, 219-224, 226-237, 232-245, 248-261, 261-268, 272-283, 279-290, 298-307, 307-314, 323-331, 333-344, 344-355, 367-375, and 374-386 of TP53.

[933] In some embodiments of identifying the presence of a cancer in a human subject, the one or more protein biomarkers include CA19-9. In some embodiments, the reference level of the CA19-9 protein biomarker is 92 U/mL. In some embodiments, the one or more protein biomarkers include CEA. In some embodiments, the reference level of the CEA protein biomarker is 7.5 ng/mL. In some embodiments, the one or more protein biomarkers include HGF. In some embodiments, the reference level of the HGF protein biomarker is 0.89 ng/mL. In some embodiments, the one or more protein biomarkers include OPN. In some embodiments, the reference level of the OPN protein biomarker is 158 ng/mL. In some embodiments, the one or more protein biomarkers include CA125. In some embodiments, the reference level of the CA125 protein biomarker is 577 U/mL. In some embodiments, the one or more protein biomarkers include AFP. In some embodiments, the reference level of the AFP protein biomarker is 21 ng/mL. In some embodiments, the one or more protein biomarkers include prolactin. In some embodiments, the reference level of the prolactin protein biomarker is 145 ng/mL. In some embodiments, the one or more protein biomarkers include TIMP-1. In some embodiments, the reference level of the TIMP-1 protein biomarker

is 177ng/mL. In some embodiments, the one or more protein biomarkers include follistatin. In some embodiments, the reference level of the follistatin protein biomarker is 2 ng/mL. In some embodiments, the one or more protein biomarkers include G-CSF. In some embodiments, the reference level of the G-CSF protein biomarker is 800 pg/mL. In some embodiments, the one or more protein biomarkers include CA15-3. In some embodiments, the reference level of the CA15-3 protein biomarker is 98 U/mL.

[934] In some embodiments of identifying the presence of a cancer in a human subject, the presence of one or more genetic alterations in cell-free DNA in the first biological sample, the absence of one or more genetic alterations in DNA in the second biological sample, or both are detected by amplifying the cell-free DNA to form families of amplicons in which each member of a family is derived from a single template molecule in the cell-free DNA, wherein each member of a family is marked by a common oligonucleotide barcode, and wherein each family is marked by a distinct oligonucleotide barcode. In some embodiments, the oligonucleotide barcode is introduced into the template molecule by a step of amplifying with a population of primers which collectively contain a plurality of oligonucleotide barcodes. In some embodiments, the oligonucleotide barcode is endogenous to the template molecule, and an adapter comprising a DNA synthesis priming site is ligated to an end of the template molecule adjacent to the oligonucleotide barcode.

[935] In some embodiments, a therapeutic intervention is administered to the subject when the presence of cancer is identified. In some embodiments, the therapeutic intervention is selected from the group consisting of: adoptive T cell therapy, radiation therapy, surgery, administration of a chemotherapeutic agent, administration of an immune checkpoint inhibitor, administration of a targeted therapy, administration of a kinase inhibitor, administration of a signal transduction inhibitor, administration of a bispecific antibody, administration of a monoclonal antibody, and combinations thereof. In some embodiments, the therapeutic intervention is administered at a time when the subject has an early-stage cancer, and wherein the therapeutic intervention is more effective than if the therapeutic intervention were to be administered to a subject at a later time.

[936] In some embodiments of identifying the presence of a cancer in a human subject, the presence of cancer in the subject is detected at a time prior to diagnosis of the subject with cancer. In some embodiments, the presence of cancer in the subject is detected at a time prior to the subject exhibiting symptoms associated with cancer.

[937] In some embodiments of identifying the presence of a cancer in a human subject, the human subject is human subjected to a radiologic scanning of an organ or body region to identify the location of the cancer. In some embodiments, the human subject is human subjected to whole body radiologic scanning to identify the location of the cancer. In some embodiments, the scanning is a Positron emission tomography-computed tomography (PET-CT) scan.

[938] In some embodiments of identifying the presence of a cancer in a human subject, the cancer is selected from the group consisting of: pancreatic cancer, colon cancer, esophageal cancer, stomach cancer, ovarian cancer, liver cancer, lung cancer, and breast cancer, and combinations thereof.

[939] As described in more detail herein, it has been shown that DNA from sampled fluid (e.g., fluid containing cells sampled from the endocervical canal) can be used in an assay (e.g., a PCR-based, multiplex test) to simultaneously assess genetic alterations that commonly occur in endometrial or ovarian cancers (Fig. 19). Additionally, as described in more detail herein and without limitation, two ways to increase sensitivity were identified. First, intrauterine sampling (with a "Tao brush") was tested, a method that allows sample collection closer to the anatomical site of the tumors. Second, in a recent study, it was shown that testing for mutations in both saliva and plasma from the same individual increased the sensitivity of detecting head and neck tumors (Wang et al., Detection of somatic mutations and HPV in the saliva and plasma of patients with head and neck squamous cell carcinomas. Sci Transl Med 7, 293ra104 (2015)). Based on this precedent, it was shown that testing for mutations in both the plasma and Pap test fluid can increase sensitivity for cancers (e.g., ovarian cancers).

[940] In some aspects, provided herein are methods of detecting endometrial and ovarian cancers based on genetic analyses of DNA recovered from fluids (e.g., fluids obtained during

a routine Papanicolaou (Pap) test). In some embodiments, this new test, called PapSEEK, incorporates assays for mutations in one or more of 18 genes and/or an assay for aneuploidy. In some embodiment, method provided herein to detect gynecologic cancers are used at a stage when the cancers are more likely to be curable. In some embodiments, PapSEEK can be combined with assays for mutations in one or more genes in nucleic acids present in a plasma sample.

[941] In some embodiments, provided herein are methods of detecting ovarian or endometrial cancer in a subject that include detecting in a sample obtained from the subject the presence of one or more mutations in one or more genes selected from the group consisting of: NRAS, PTEN, FGFR2, KRAS, POLE, AKT1, TP53, RNF43, PPP2R1A, MAPK1, CTNNB1, PIK3CA, FBXW7, PIK3R1, APC, EGFR, BRAF, and CDKN2A, detecting in the sample the presence of aneuploidy, or both, wherein the presence of one or more mutations in NRAS, PTEN, FGFR2, KRAS, POLE, AKT1, TP53, RNF43, PPP2R1A, MAPK1, CTNNB1, PIK3CA, FBXW7, PIK3R1, APC, EGFR, BRAF, or CDKN2A, the presence of aneuploidy, or both indicates that the subject has ovarian or endometrial cancer. In some embodiments, the step of detecting the presence of one or more mutations in NRAS, PTEN, FGFR2, KRAS, POLE, AKT1, TP53, RNF43, PPP2R1A, MAPK1, CTNNB1, PIK3CA, FBXW7, PIK3R1, APC, EGFR, BRAF, CDKN2A is performed using a PCR-based multiplex assay, using a PCR-based singleplex assay, a digital PCR assay, a droplet digital PCR (ddPCR) assay, a microarray assay, a next-generation sequencing assay, a Sanger sequencing assay, a quantitative PCR assay, or a ligation assay. In some embodiments, the step of detecting the presence of one or more mutations in NRAS, PTEN, FGFR2, KRAS, POLE, AKT1, TP53, RNF43, PPP2R1A, MAPK1, CTNNB1, PIK3CA, FBXW7, PIK3R1, APC, EGFR, BRAF, CDKN2A is performed by increasing the sensitivity of massively parallel sequencing instruments with an error reduction technique that allows for the detection of rare mutant alleles in a range of 1 mutant template among 100 to 1,000,000 wild-type templates. For example, the step of detecting one or more mutations can be performed by increasing the sensitivity of massively parallel sequencing instruments with an error reduction technique comprising: a) molecularly assigning a unique identifier (UID) to each template molecule, b) amplifying each uniquely tagged template molecule to create

UID-families, and c) redundantly sequencing the amplification products. In some embodiments, methods provided herein further include conducting cytology on the sample, wherein presence of the one or more mutations in NRAS, PTEN, FGFR2, KRAS, POLE, AKT1, TP53, RNF43, PPP2R1A, MAPK1, CTNNB1, PIK3CA, FBXW7, PIK3R1, APC, EGFR, BRAF, or CDKN2A, the presence of aneuploidy, and/or a positive cytology indicates that the subject has ovarian or endometrial cancer. In some embodiments, the step of detecting in the sample the presence of aneuploidy comprises detecting the presence of one or more alterations on one or more of chromosome arms 4p, 7q, 8q, and 9q. In some embodiments, the step of detecting in the sample the presence of aneuploidy comprises amplifying interspersed nucleotide elements. In some embodiments, methods provided herein further include detecting in a second sample comprising circulating tumor DNA (ctDNA) the presence of at least one mutation in one or more genes selected from the group consisting of: AKT1, APC, BRAF, CDKN2A, CTNNB1, EGFR, FBXW7, FGFR2, GNAS, HRAS, KRAS, NRAS, PIK3CA, PPP2R1A, PTEN, and TP53. In some embodiments, the second sample includes plasma. In some embodiments, the sample is collected via intrauterine sampling. In some embodiments, the sample is collected with a Tao brush. In some embodiments, methods further include administering to the subject a therapy (e.g., adjuvant chemotherapy, neoadjuvant chemotherapy, radiation therapy, immunotherapy, targeted therapy, immune checkpoint inhibitors, and combinations thereof).

[942] In some embodiments, provided herein are methods of detecting endometrial cancer in a subject that include detecting in a sample obtained from the subject the presence of one or more mutations in one or more genes selected from the group consisting of: PTEN, TP53, PIK3CA, PIK3R1, CTNNB1, KRAS, FGFR2, POLE, APC, FBXW7, RNF43, and PPP2R1A, detecting in the sample the presence of aneuploidy, or both, wherein the presence of one or more mutations in PTEN, TP53, PIK3CA, PIK3R1, CTNNB1, KRAS, FGFR2, POLE, APC, FBXW7, RNF43, and PPP2R1A, the presence of aneuploidy, or both indicates that the subject has endometrial cancer. In some embodiments, the step of detecting the presence of one or more mutations in PTEN, TP53, PIK3CA, PIK3R1, CTNNB1, KRAS, FGFR2, POLE, APC, FBXW7, RNF43, and PPP2R1A is performed using a PCR-based multiplex assay, using a PCR-based singleplex assay, a digital PCR assay, a droplet digital

PCR (ddPCR) assay, a microarray assay, a next-generation sequencing assay, a Sanger sequencing assay, a quantitative PCR assay, or a ligation assay. In some embodiments, the step of detecting the presence of one or more mutations in PTEN, TP53, PIK3CA, PIK3R1, CTNNB1, KRAS, FGFR2, POLE, APC, FBXW7, RNF43, and PPP2R1A is performed by increasing the sensitivity of massively parallel sequencing instruments with an error reduction technique that allows for the detection of rare mutant alleles in a range of 1 mutant template among 100 to 1,000,000 wild-type templates. For example, the step of detecting one or more mutations can be performed by increasing the sensitivity of massively parallel sequencing instruments with an error reduction technique comprising: a) molecularly assigning a unique identifier (UID) to each template molecule, b) amplifying each uniquely tagged template molecule to create UID-families, and c) redundantly sequencing the amplification products. In some embodiments, methods provided herein further include conducting cytology on the sample, wherein presence of the one or more mutations in PTEN, TP53, PIK3CA, PIK3R1, CTNNB1, KRAS, FGFR2, POLE, APC, FBXW7, RNF43, and PPP2R1A, the presence of aneuploidy, and/or a positive cytology indicates that the subject has endometrial cancer. In some embodiments, the step of detecting in the sample the presence of aneuploidy comprises detecting the presence of one or more alterations on one or more of chromosome arms 4p, 7q, 8q, and 9q. In some embodiments, the step of detecting in the sample the presence of aneuploidy comprises amplifying interspersed nucleotide elements. In some embodiments, methods provided herein further include detecting in a second sample comprising circulating tumor DNA (ctDNA) the presence of at least one mutation in one or more genes selected from the group consisting of: AKT1, APC, BRAF, CDKN2A, CTNNB1, EGFR, FBXW7, FGFR2, GNAS, HRAS, KRAS, NRAS, PIK3CA, PPP2R1A, PTEN, and TP53. In some embodiments, the second sample includes plasma. In some embodiments, the sample is collected via intrauterine sampling. In some embodiments, the sample is collected with a Tao brush. In some embodiments, methods further include administering to the subject a therapy (e.g., adjuvant chemotherapy, neoadjuvant chemotherapy, radiation therapy, immunotherapy, targeted therapy, immune checkpoint inhibitors, and combinations thereof).

[943] In some embodiments, provided herein are methods of detecting ovarian cancer in a subject that include detecting in a sample obtained from the subject the presence of one or more mutations in TP53, detecting in the sample the presence of aneuploidy, or both, wherein the presence of one or more mutations in TP53, the presence of aneuploidy, or both indicates that the subject has ovarian cancer. In some embodiments, the step of detecting the presence of one or more mutations in TP53 is performed using a PCR-based multiplex assay, using a PCR-based singleplex assay, a digital PCR assay, a droplet digital PCR (ddPCR) assay, a microarray assay, a next-generation sequencing assay, a Sanger sequencing assay, a quantitative PCR assay, or a ligation assay. In some embodiments, the step of detecting the presence of one or more mutations in TP53 is performed by increasing the sensitivity of massively parallel sequencing instruments with an error reduction technique that allows for the detection of rare mutant alleles in a range of 1 mutant template among 100 to 1,000,000 wild-type templates. For example, the step of detecting one or mutations can be performed by increasing the sensitivity of massively parallel sequencing instruments with an error reduction technique comprising: a) molecularly assigning a unique identifier (UID) to each template molecule, b) amplifying each uniquely tagged template molecule to create UID-families, and c) redundantly sequencing the amplification products. In some embodiments, methods provided herein further include conducting cytology on the sample, wherein presence of the one or more mutations in TP53, the presence of aneuploidy, and/or a positive cytology indicates that the subject has ovarian cancer. In some embodiments, the step of detecting in the sample the presence of aneuploidy comprises detecting the presence of one or more alterations on one or more of chromosome arms 4p, 7q, 8q, and 9q. In some embodiments, the step of detecting in the sample the presence of aneuploidy comprises amplifying interspersed nucleotide elements. In some embodiments, methods provided herein further include detecting in a second sample comprising circulating tumor DNA (ctDNA) the presence of at least one mutation in one or more genes selected from the group consisting of: AKT1, APC, BRAF, CDKN2A, CTNNB1, EGFR, FBXW7, FGFR2, GNAS, HRAS, KRAS, NRAS, PIK3CA, PPP2R1A, PTEN, and TP53. In some embodiments, the second sample includes plasma. In some embodiments, the sample is collected via intrauterine sampling. In some embodiments, the sample is collected with a Tao brush. In

some embodiments, methods further include administering to the subject a therapy (e.g., adjuvant chemotherapy, neoadjuvant chemotherapy, radiation therapy, immunotherapy, targeted therapy, immune checkpoint inhibitors, and combinations thereof).

[944] Provided herein are methods of detecting bladder cancer or an upper tract urothelial carcinoma in a subject that include: detecting in a urinary sample obtained from the subject the presence of one or more mutations in one or more genes selected from the group consisting of: TP53, PIK3CA, FGFR3, KRAS, ERBB2, CDKN2A, MLL, HRAS, MET, and VHL, detecting in the sample the presence of at least one mutation in a TERT promoter, and detecting in the sample the presence of aneuploidy, wherein presence of one or more mutations in the group consisting of: TP53, PIK3CA, FGFR3, KRAS, ERBB2, CDKN2A, MLL, HRAS, MET, and VHL, the presence of the at least one mutation in the TERT promoter, or the presence of aneuploidy indicates that the subject has bladder cancer. In some embodiments of methods of detecting bladder cancer or an upper tract urothelial carcinoma in a subject, the one or more genes are TP53, FGFR3, or both. In some embodiments of methods of detecting bladder cancer or an upper tract urothelial carcinoma in a subject, the one or more mutations in TP53, PIK3CA, FGFR3, KRAS, ERBB2, CDKN2A, MLL, HRAS, MET, or VHL, the one or more mutations in the TERT promoter, or both, are present in 0.03% or fewer of the urinary cells in the sample.

[945] In some embodiments of methods of detecting bladder cancer or an upper tract urothelial carcinoma in a subject, the step of detecting the presence of one or more mutations in TP53, PIK3CA, FGFR3, KRAS, ERBB2, CDKN2A, MLL, HRAS, MET, VHL, the step of detecting the presence of at least one mutation in the TERT promoter, or both is performed using a PCR based multiplex assay, a Sanger sequencing assay, a next-generation sequencing assay, a quantitative PCR assay, a droplet digital PCR (ddPCR) assay, or a microarray technique. In some embodiments of methods of detecting bladder cancer or an upper tract urothelial carcinoma in a subject, the step of detecting the presence of one or more mutations in TP53, PIK3CA, FGFR3, KRAS, ERBB2, CDKN2A, MLL, HRAS, MET, VHL, the step of detecting the presence of at least one mutation in the TERT promoter, or both is performed using a Sanger Sequencing assay. In some embodiments of methods of detecting bladder cancer or an upper tract urothelial carcinoma in a subject, the step of detecting the presence

of one or more mutations in TP53, PIK3CA, FGFR3, KRAS, ERBB2, CDKN2A, MLL, HRAS, MET, VHL, the step of detecting the presence of at least one mutation in the TERT promoter, or both is performed using a next generation sequencing assay.

[946] In some embodiments of methods of detecting bladder cancer or an upper tract urothelial carcinoma in a subject, the step of detecting in the sample the presence of aneuploidy comprises detecting the presence of one or more alterations on one or more of chromosome arms 5q, 8q, and 9p. In some embodiments of methods of detecting bladder cancer or an upper tract urothelial carcinoma in a subject, the step of detecting the presence of aneuploidy comprises amplifying long interspersed nucleotide elements (LINESs).

[947] In some embodiments of methods of detecting bladder cancer or an upper tract urothelial carcinoma in a subject, the step of detecting the presence of one or more mutations in TP53, PIK3CA, FGFR3, KRAS, ERBB2, CDKN2A, MLL, HRAS, MET, VHL, the step of detecting the presence of at least one mutation in the TERT promoter, or both is performed by increasing the sensitivity of massively parallel sequencing instruments with an error reduction technique that allows for the detection of rare mutant alleles in a range of 1 mutant template among 5,000 to 1,000,000 wild-type templates. In some embodiments of methods of detecting bladder cancer or an upper tract urothelial carcinoma in a subject, the step of detecting the presence of one or more mutations in TP53, PIK3CA, FGFR3, KRAS, ERBB2, CDKN2A, MLL, HRAS, MET, VHL, the step of detecting the presence of at least one mutation in the TERT promoter, or both is performed by increasing the sensitivity of massively parallel sequencing instruments with an error reduction technique that includes: a) assigning a unique identifier (UID) to each template molecule, b) amplifying each uniquely tagged template molecule to create UID-families, and c) redundantly sequencing the amplification products.

[948] In some embodiments of methods of detecting bladder cancer or an upper tract urothelial carcinoma in a subject, the method further includes performing cytology on the sample, wherein presence of the one or more mutations in TP53, PIK3CA, FGFR3, KRAS, ERBB2, CDKN2A, MLL, HRAS, MET, VHL, the presence of the at least one mutation in the TERT promoter, the presence of aneuploidy, or a positive cytology indicates that the subject has bladder cancer.

[949] In some embodiments of methods of detecting bladder cancer in a subject, the method further includes administering transuretral resection of the bladder (TURB), intravesical BCG (Bacillus Calmette-Guerin), intravesical chemotherapy, adjuvant chemotherapy, neoadjuvant chemotherapy, cystectomy or cystoprostatectomy, radiation therapy, immunotherapy, immune checkpoint inhibitors, or any combination thereof.

[950] In some embodiments of methods of detecting an upper tract urothelial carcinoma in a subject, the method further includes administering transurethral resection, intravesical BCG (Bacillus Calmette-Guerin), intravesical chemotherapy, adjuvant chemotherapy, neoadjuvant chemotherapy, ureterectomy or nephroureterectomy, radiation therapy, immunotherapy, immune checkpoint inhibitors, or any combination thereof.

[951] In some embodiments of methods of detecting bladder cancer or an upper tract urothelial carcinoma in a subject, the cancer is a low-grade tumor. In some embodiments of methods of detecting bladder cancer or an upper tract urothelial carcinoma in a subject in which the cancer is a low-grade tumor, the low-grade tumor is a papillary urothelial neoplasms of low malignant potential (PUNLMP) or a non-invasive low grade papillary urothelial carcinoma. In some embodiments of methods of detecting bladder cancer or an upper tract urothelial carcinoma in a subject in which the cancer is a low-grade tumor, the method further includes administering transuretral resection of the bladder (TURB).

[952] In some embodiments of methods of detecting bladder cancer or an upper tract urothelial carcinoma in a subject, the subject has previously undergone treatment for bladder cancer or an upper tract urothelial carcinoma. In some embodiments of methods of detecting bladder cancer or an upper tract urothelial carcinoma in a subject in which the subject has previously undergone treatment for bladder cancer or an upper tract urothelial carcinoma, the method includes detecting in a urinary sample obtained from the subject the presence of one or more mutations in TP53, FGFR3, or both. In some embodiments of methods of detecting bladder cancer or an upper tract urothelial carcinoma in a subject in which the subject has previously undergone treatment for bladder cancer or an upper tract urothelial carcinoma, one or more mutations in TP53, PIK3CA, FGFR3, KRAS, ERBB2, CDKN2A, MLL, HRAS, MET, or VHL, one or more mutations in the TERT promoter, or both, are present in 0.03% or fewer of the urinary cells in the sample. In some embodiments of methods of detecting

bladder cancer or an upper tract urothelial carcinoma in a subject in which the subject has previously undergone treatment for bladder cancer or an upper tract urothelial carcinoma, the step of detecting the presence of one or more mutations in TP53, PIK3CA, FGFR3, KRAS, ERBB2, CDKN2A, MLL, HRAS, MET, VHL, the step of detecting the presence of at least one mutation in the TERT promoter, or both is performed using a PCR based multiplex assay. In some embodiments of methods of detecting bladder cancer or an upper tract urothelial carcinoma in a subject in which the subject has previously undergone treatment for bladder cancer or an upper tract urothelial carcinoma, the step of detecting the presence of one or more mutations in TP53, PIK3CA, FGFR3, KRAS, ERBB2, CDKN2A, MLL, HRAS, MET, VHL, the step of detecting the presence of at least one mutation in the TERT promoter, or both is performed using a Sanger Sequencing assay. In some embodiments of methods of detecting bladder cancer or an upper tract urothelial carcinoma in a subject in which the subject has previously undergone treatment for bladder cancer or an upper tract urothelial carcinoma, the step of detecting the presence of one or more mutations in TP53, PIK3CA, FGFR3, KRAS, ERBB2, CDKN2A, MLL, HRAS, MET, VHL, the step of detecting the presence of at least one mutation in the TERT promoter, or both is performed using a next generation sequencing assay.

[953] In some embodiments of methods of detecting bladder cancer or an upper tract urothelial carcinoma in a subject in which the subject has previously undergone treatment for bladder cancer or an upper tract urothelial carcinoma, the step of detecting in the sample the presence of aneuploidy comprises detecting the presence of one or more alterations on one or more of chromosome arms 5q, 8q, and 9p. In some embodiments of methods of detecting bladder cancer or an upper tract urothelial carcinoma in a subject in which the subject has previously undergone treatment for bladder cancer or an upper tract urothelial carcinoma, the step of detecting the presence of aneuploidy comprises amplifying long interspersed nucleotide elements (LINESs).

[954] In some embodiments of methods of detecting bladder cancer or an upper tract urothelial carcinoma in a subject in which the subject has previously undergone treatment for bladder cancer or an upper tract urothelial carcinoma, the step of detecting the presence of one or more mutations in TP53, PIK3CA, FGFR3, KRAS, ERBB2, CDKN2A, MLL, HRAS,

MET, VHL, the step of detecting the presence of at least one mutation in the TERT promoter, or both is performed by increasing the sensitivity of massively parallel sequencing instruments with an error reduction technique that allows for the detection of rare mutant alleles in a range of 1 mutant template among 5,000 to 1,000,000 wild-type templates. In some embodiments of methods of detecting bladder cancer or an upper tract urothelial carcinoma in a subject in which the subject has previously undergone treatment for bladder cancer or an upper tract urothelial carcinoma, the step of detecting the presence of one or more mutations in TP53, PIK3CA, FGFR3, KRAS, ERBB2, CDKN2A, MLL, HRAS, MET, VHL, the step of detecting the presence of at least one mutation in the TERT promoter, or both is performed by increasing the sensitivity of massively parallel sequencing instruments with an error reduction technique that includes: a) assigning a unique identifier (UID) to each template molecule, b) amplifying each uniquely tagged template molecule to create UID-families, and c) redundantly sequencing the amplification products.

[955] In some embodiments of methods of detecting bladder cancer or an upper tract urothelial carcinoma in a subject in which the subject has previously undergone treatment for bladder cancer or an upper tract urothelial carcinoma, the method further includes conducting cytology on the sample, wherein presence of the one or more mutations in TP53, PIK3CA, FGFR3, KRAS, ERBB2, CDKN2A, MLL, HRAS, MET, VHL, the presence of the at least one mutation in the TERT promoter, the presence of aneuploidy, or a positive cytology indicates that the subject has bladder cancer.

[956] In some embodiments of methods of detecting bladder cancer in a subject in which the subject has previously undergone treatment for bladder cancer or an upper tract urothelial carcinoma, the method further includes administering transuretral resection of the bladder (TURB), intravesical BCG (Bacillus Calmette-Guerin), intravesical chemotherapy, adjuvant chemotherapy, neoadjuvant chemotherapy, cystectomy or cystoprostatectomy, radiation therapy, immunotherapy, immune checkpoint inhibitors, or any combinations of the above.

[957] In some embodiments of methods of detecting an upper tract urothelial carcinoma in a subject in which the subject has previously undergone treatment for bladder cancer or an upper tract urothelial carcinoma, the method further includes administering transurethral resection, intravesical BCG (Bacillus Calmette-Guerin), intravesical chemotherapy, adjuvant

chemotherapy, neoadjuvant chemotherapy, ureterectomy or nephroureterectomy, radiation therapy, immunotherapy, immune checkpoint inhibitors, or any combination thereof.

[958] This document provides methods and materials for identifying one or more chromosomal anomalies (e.g., aneuploidy). In some cases, this document provides methods and materials for using amplicon-based sequencing data to identify a mammal as having a disease or disorder associated with one or more chromosomal anomalies. For example, methods and materials described herein can be applied to a sample obtained from a mammal to identify the mammal as having one or more chromosomal anomalies. For example, methods and materials described herein can be applied to a sample obtained from a mammal to identify the mammal as having a disease or disorder associated with one or more chromosomal anomalies. For example, a prenatal mammal can be identified as having a disease or disorder based, at least in part, on the presence of one or more aneuploidies. This document also provides methods and materials for identifying and/or treating a disease associated with one or more chromosomal anomalies. In some cases, one or more chromosomal anomalies can be identified in DNA obtained from a sample obtained from a mammal. For example, a mammal identified as having cancer based, at least in part, on the presence of one or more chromosomal anomalies can be treated with one or more cancer treatments.

[959] As demonstrated herein, a new approach (called WALDO for **W**ithin-**S**ample-**A**neup**L**oidy-**D**etecti**O**n, can be used to evaluate the sequencing data obtained from amplicons to identify the presence of one or more chromosomal anomalies (e.g., aneuploidy). For example, WALDO can employ supervised machine learning to detect the small changes in multiple chromosome arms that are often present in cancers. As described herein, WALDO was used to search for chromosome arm gains and losses in 1,677 tumors as well as in 1,522 liquid biopsies of blood from cancer patients or normal individuals. Aneuploidy was detected in 95% of cancer biopsies and in 22% of liquid biopsies. Using single nucleotide polymorphisms (SNPs) within the amplified interspersed nucleotide elements (LINEs), WALDO concomitantly assessed allelic imbalances, microsatellite instability, and sample identification. WALDO can be used on samples containing only a few nanograms (ng) of DNA and having as little as 1% neoplastic content.

[960] Having the ability to use amplicon-based sequencing reads to detect one or more chromosomal anomalies provides a unique and unrealized opportunity to achieve high coverage depth with improved sensitivity at relatively low cost. Moreover, the ability to use amplicon-based sequencing reads allows the detection of one or more chromosomal anomalies (e.g., aneuploidies) from samples containing limited amounts of DNA. This approach can be used in a variety of applications including, but not limited to, diagnostics (e.g., prenatal diagnostics and/or cancer diagnostics) and forensic science.

[961] In general, one aspect of this document features a method for detecting aneuploidy in a genome of a mammal. The method includes, or consists essentially of, sequencing a plurality of amplicons obtained from a sample obtained from the mammal to obtain sequencing reads; grouping the sequencing reads into clusters of genomic intervals; calculating sums of distributions of the sequencing reads in each genomic interval using the equation $\sum_1^I R_i \sim N(\sum_1^I \mu_i, \sum_1^I \sigma_i^2)$, where R_i is the number of sequencing reads, I is the number of clusters on a chromosome arm, N is a Gaussian distribution with parameters μ_i and σ_i^2, where μ_i is the mean number of sequencing reads in each genomic interval, and where σ_i^2 is the variance of sequencing reads in each genomic interval; calculating a Z-score of a chromosome arm using the quantile function 1-CDF($\sum_1^I \mu_i, \sum_1^I \sigma_i^2$); and identifying the presence of an aneuploidy in the genome of the mammal when the Z-score is outside a significance threshold. The plurality of amplicons can include from about 10,000 amplicons to about 1,000,000 amplicons (e.g., the plurality of amplicons can include about 38,000 amplicons). The genomic intervals can include from about 100 nucleotides to about 125,000,000 nucleotides (e.g., the genomic intervals can include about 500,000 nucleotides). The mammal can be a human. The sample can be a liquid biopsy. The liquid biopsy can be blood, urine, saliva, cyst fluid, sputum, tissue, stool, pap smears, or cerebral spinal fluid. The liquid biopsy can be a blood sample (e.g., a plasma sample). The blood sample can include cell free fetal DNA. The sample can include a neoplastic cell fraction. The neoplastic cell fraction in the sample can include less than about 1% (e.g., less than about 0.5%) of the entire sample. The amplicons can include unique long interspersed nucleotide elements (LINEs). The sequencing step also can include amplifying DNA from the sample obtained from the mammal to obtain the amplicons. The amplifying can be performed using a single

primer pair. The amplicons can include about 100 to about 140 base pairs. Each amplicon can be sequenced between 1 and 20 times. The method can include about 100,000 to about 25 million sequencing reads. Each cluster can include about two hundred genomic intervals. The method also can include supervised machine learning. The supervised machine learning can employ a support vector machine model.

[962] In another aspect, this document features a method for detecting one or more polymorphisms in a genome of a mammal. The method includes, or consists essentially of, sequencing a plurality of amplicons obtained from a sample from the mammal to obtain variant sequencing reads; sequencing a plurality of amplicons obtained from a reference sample from the mammal to obtain reference sequencing reads; grouping the variant sequencing reads and the reference sequencing reads into clusters of genomic intervals; selecting a chromosome arm having a sum of the variant sequencing reads and the reference sequencing reads on both alleles that is greater than about 3; determining a variant-allele frequency (VAF) of the selected chromosome arm, wherein said VAF is the number of variant sequencing reads / total number of sequencing reads; and identifying the presence of one or more polymorphisms on said selected chromosome arm of the mammal if the VAF is between about 0.2 and about 0.8. The sequencing step can include assigning a unique identifier (UID) to each amplicon, amplifying each uniquely tagged amplicon to create UID-families, and redundantly sequencing the amplification products. The sequencing step can further include calculating a Z-score of a variant on said selected chromosome arm using the equation $Z \sim \frac{\sum_{i=1}^{k} w_i Z_i}{\sqrt{\sum_{i=1}^{k} w_i^2}}$, where w_i is UID depth at a variant i, Z_i is the Z-score of variant i, and k is the number of variants observed on the chromosome arm. The one or more polymorphisms can include single base substitutions, insertions, deletions, indels, and/or combinations thereof. The pluralities of amplicons can include from about 10,000 amplicons to about 1,000,000 amplicons (e.g., the pluralities of amplicons can include about 38,000 amplicons). The genomic intervals can include from about 100 nucleotides to about 125,000,000 nucleotides (e.g., the genomic intervals can include about 500,000 nucleotides). The mammal can be a human. The sample can be a liquid biopsy. The liquid biopsy can be blood, urine, saliva, cyst fluid, sputum, tissue, stool, pap smears, or cerebral spinal fluid. The

liquid biopsy can be a blood sample (e.g., a plasma sample). The blood sample can include cell free fetal DNA. The sample can include a neoplastic cell fraction. The neoplastic cell fraction in the sample can include less than about 1% (e.g., less than about 0.5%) of the entire sample. The amplicons can include unique long interspersed nucleotide elements (LINEs). The sequencing step also can include amplifying DNA from the sample obtained from the mammal to obtain the amplicons. The amplifying can be performed using a single primer pair. The amplicons can include about 100 to about 140 base pairs. Each amplicon can be sequenced between 1 and 20 times. The method can include about 100,000 to about 25 million sequencing reads. Each cluster can include about two hundred genomic intervals. The method also can include supervised machine learning. The supervised machine learning can employ a support vector machine model.

OTHER EMBODIMENTS

[963] It is to be understood that while the invention has been described in conjunction with the detailed description thereof, the foregoing description is intended to illustrate and not limit the scope of the invention, which is defined by the scope of the appended claims. Other aspects, advantages, and modifications are within the scope of the following claims.

EXAMPLES

Example 1: Detection and localization of surgically resectable cancers with a multi-analyte liquid biopsy

[964] Many of the currently approved tests for earlier cancer detection are procedural in nature, and include colonoscopy, mammography, and cervical cytology analysis. To date, the vast majority of cancer patients evaluated with mutation-based liquid biopsies have advanced stage disease. Yet another issue with liquid biopsies is the identification of the underlying organ of origin. Because the same gene mutations drive multiple tumor types, liquid biopsies based on such alterations cannot generally identify the location of the primary tumor giving rise to a positive blood test.

[965] This Example describes a new blood test, called CancerSEEK, which addresses the problematic issues described above. The test utilizes combined assays for genetic alterations and protein biomarkers and has the capacity not only to identify the presence of relatively early cancers but also to pinpoint the organ of origin of these cancers (Fig. 1).

[966] CancerSEEK is a widely applicable, non-invasive test for most cancers. The eight cancer types studied here account for 360,000 (60%) of the estimated cancer deaths in the U.S. in 2017 and their earlier detection could conceivably reduce deaths from these diseases. At the time of this disclosure, the cost of CancerSEEK is less than $500, which is comparable or lower than other screening tests for *single* cancers, such as colonoscopy, while this test can detect at least eight different cancer types.

Materials and Methods

Plasma, white blood cell and tumor DNA samples

[967] The study was approved by the Institutional Review Boards for Human Research at each institution, and samples were obtained after informed consent was obtained. Patients with stage I to III cancer, who had undergone surgical resection at the participating institutions were included in the study. Blood was collected from patients before any therapy was undertaken (i.e., before neoadjuvant therapy in those patients receiving neoadjuvant therapy) and before surgery in all patients. If sample was drawn on the day of surgery, then care was taken to ensure that the blood was collected prior to the administration of anesthesia, as anesthesia can increase the levels of circulating biomarkers (Cohen *et al.*, 2017 *Proc Natl Acad Sci U S A* 114:10202-10207). General demographics, surgical pathology, and AJCC stage (7^{th} edition) were documented. The 'healthy' cohort consisted of peripheral blood samples obtained from 812 individuals of median age 55 (IQR interquartile range 28 to 65) with no history of cancer. The cancer and healthy control samples were processed in an identical manner. Plasma samples from 46 of the 1,005 cancer patients and 181 of the 812 normal samples had been previously evaluated with a different approach (Cohen *et al.*, 2017 *Proc Natl Acad Sci U S A* 114:10202-10207) (Table 2).

[968] DNA was purified from an average of 7.5 mL plasma using a QIASymphony circulating DNA kit (cat # 1091063), as specified by the manufacturer. DNA from peripheral WBCs was also purified with the QIAsymphony DP DNA Midi Kit (Cat # 937255) as specified by the manufacturer. Tumor tissues were formalin-fixed and paraffin-embedded (FFPE) according to standard histopathologic procedures and also purified with a QIAsymphony DP DNA Midi Kit (Cat # 937255).

Mutation detection and analysis

[969] For amplification of DNA from plasma, 61 primer pairs were designed (see below) to amplify 66 to 80 bp segments containing regions of interest from 16 genes.

[970] The 61 primer pairs were divided into two non-overlapping sets each containing either 28 or 33 primer pairs. Each of these two primer sets were used to amplify DNA in six independent 25 µl reactions as described elsewhere (see, e.g., Wang *et al.*, 2016 *Elife* 5) except that 15 cycles were used for the initial amplification. The PCR products were purified with AMPure XP beads (Beckman Coulter, PA, USA) and 1% of the purified PCR products were then amplified in a second round of PCR as described elsewhere (see, e.g., Wang *et al.*, 2016 *Elife* 5), but using 21 cycles. PCR products from the second round of amplification were then purified with AMPure and sequenced on an Illumina MiSeq or HiSeq 4000 instrument.

[971] The template-specific portion of the reads was matched to reference sequences using custom scripts written in SQL and C#. Reads from a common template molecule were then grouped based on the unique identifier sequences (UIDs) that were incorporated as molecular barcodes as described elsewhere (see, e.g., Kinde et al., 2011 *Proc Natl Acad Sci U S A* 108:9530-9535). Artefactual mutations introduced during the sample preparation or sequencing steps were reduced by requiring a mutation to be present in > 90% of reads in each UID family. Redundant reads arising from optical duplication were eliminated by requiring reads with the same UID and sample index to be at least 5,000 pixels apart when located on the same tile. Mutations that met one of the two following criteria were considered (i) present in the COSMIC database (Forbes *et al.*, 2017 *Nucleic Acids Res* 45:D777-D783), or (ii) predicted to be inactivating in tumor suppressor genes (nonsense mutations, out-of-

frame insertions or deletions, canonical splice site mutations). Synonymous mutations, except those at exon ends, and intronic mutations, except for those at splice sites, were excluded.

Evaluation of plasma proteins

[972] The Bioplex 200 platform (Biorad, Hercules CA) was used to determine the concentration of multiple target proteins in the plasma samples. Luminex bead based immunoassays (Millipore, Bilerica NY) were performed following the manufacturers protocols and concentrations were determined using 5 parameter log curve fits (using Bioplex Manager 6.0) with vendor provided standards and quality controls. The HCCBP1MAG-58K panel was used to detect FGF2, Osteopontin, sFas, IL-8/CXCL8, Prolactin, HE4, HGF, AFP, CA125, IL6, CA15-3, TGFa, CYFRA21-1, CEA, CA19-9 and Leptin. The HANG2MAG-12K panel was used to detect PAR, sPECAM-1, TSP-2, sEGFR, AXL and sHER2/sEGFR2/sErbB2. The HCMBMAG-22K panel was used to detect DKK1, GDF15, Osteoprotegerin (OPG) and Neuron-specific enolase (NSE). The HCCBP4MAG-58K panels was used to detect Kallikrein-6, CD44, Midkine and Mesothelin. The HAGP1MAG-12K panel was used to detect Follistatin, G-CSF, Angiopoietin-2 and Endoglin. The HCCBP3MAG-58K panel was used to detect SHBG, Galectin and Myeloperoxidase. The HTMP1MAG-54K panel was used to detect TIMP-1 and TIMP-2. LRG-1 and Vitronectin were not included in this study since they could not be reproducibly evaluated with a single immunoassay platform.

Algorithm for classifying ctDNA status

[973] The classification of a sample's ctDNA status was obtained from a statistical test comparing the normalized mutation frequencies of the sample of interest to the distributions of the normalized mutation frequencies of, respectively, normal and cancer samples in the training set. Specifically, the mutant allele frequency (MAF), defined as the ratio between the number of supermutants and the number of UIDs, was first normalized based on the observed

MAFs for each mutation in a set of normal controls. Following this mutation-specific normalization, the MAF of each mutation in each well was compared to two reference distributions of MAFs: 1) a distribution built from the normal control plasmas in the training set plus a set of 188 WBCs from unrelated, healthy individuals 2) a distribution built from the cancers' samples in a training set that included only mutations found in plasma that were also present with MAF > 5% in the corresponding primary tumors. Corresponding p-values, p^N and p^C, were thus obtained. For each mutation, the log ratio of these two p-values was calculated, and the minimum and maximum of these log ratios across the six wells were eliminated so that the results would be less sensitive to outliers. An "omega" score was then determined according to the following formula:

$$\Omega = \sum_{i=1}^{4} w_i * \ log \frac{p_i^C}{p_i^N} ,$$

where w_i is the proportion of UIDs in well i out of the total number of UIDs for that mutation present across the four wells. When a mutation identified in a plasma sample had $\Omega > 1$, and was not identified in the primary tumor of the patient, DNA from white blood cells (WBCs) of the same patient whenever WBCs were available (23% of the cancer patients was evaluated. WBC DNA was tested with the same 61-amplicon panel to ensure that the plasma mutation was not a result of Clonal Hematopoiesis of Indeterminate Potential (Jaiswal et al., 2014 *N Engl J Med* 371:2488-2498). WBCs from the normal individuals were evaluated identically whenever a mutation with $\Omega > 1$ was found in the plasma. Any mutation that was identified in the WBCs as well as in the plasma was excluded from the analysis. The requirement for exclusion was that the ratio between the max MAF in the plasma and the max MAF in the WBC was less than 100.

[974] The mutation with the greatest Ω score in each patient or normal control was then deemed the "top mutation" and is listed in Table 3. This score was used in the logistic regression as well as the concentrations of the following 10 proteins, selected via an optimization step, Prolactin, OPN, IL6, CEA, CA125, HGF, Myeloperoxidase, CA19-9, Midkine, and TIMP-1. To be conservative, a non-linear transformation was applied to the

features used by Logistic Regression. Specifically, if a protein's concentration in the sample of interest was lower than the 95th percentile of the concentration found for that same protein among the normal samples in the training set, then the protein's concentration was set equal to zero; otherwise the log of that concentration was used. For the Ω score, the same log-threshold transformation was used but with a constant threshold equal to 1. The *R glmnet* package (version 2.10-13) was then used to perform the Logistic Regression, with the lambda parameter set to zero as described elsewhere (see, e.g., Friedman et al., 2010 *Journal of Statistical Software* 33:74862). The importance of each feature was evaluated by multiplying its coefficient (see below) times the difference of the feature's mean between normal and cancer samples. Ten rounds of 10-fold cross-validations were performed. The classification calls obtained in an average round of 10-fold cross-validation (CV) are listed for each of the 812 normal individuals and 1,005 cancer patients in Table 2.

Logistic regression model coefficients and importance scores.

Feature	**Logistic Regression Coefficient**	**Importance Score**
Ω score	1.77E+00	7.55E+00
CA-125	4.15E-02	1.37E+00
CEA	2.33E-04	1.17E+00

[975] For prediction of cancer type, the same 11 features (mutation score and levels of ten proteins) were used plus patient gender and the other 29 proteins evaluated in this study. Cancer type prediction was performed only on the cancer samples that were correctly classified as cancer by Logistic Regression. Random Forest, as implemented in the *randomForest* package (version 4.6-12) (see, e.g., Liaw et al., 2001 *R news* 2:18-22) was

used for this prediction. Ten rounds of 10-fold CV were performed and, for consistency, in each round and in each fold the same partition used by Logistic Regression was used by Random Forest. The classification calls obtained in an average round of 10-fold CV (the same round for which cancer status is reported in Table 3), are listed in Table 6.

[976] For determining the concordance between mutations identified in the plasma with those identified in primary tumors (Table 5), only the 155 cases in which a mutation could be identified with high confidence in the plasma were considered (Ω score > 3, Table 3) and in which the primary tumor contained any mutation that was present at a mutant allele fraction of > 5% (Table 1). This approach allowed us to avoid scoring tumors that had low neoplastic contents.

Sample identification

[977] To confirm that plasma, WBC, and primary tumor DNA samples originated from the same patient primers were utilized that could be used to amplify ~38,000 unique long interspersed nucleotide elements (LINEs) from throughout the genome as described elsewhere (see, e.g., Kinde et al., 2012 *PloS one* 7:e41162). These ~38,000 LINEs contain 26,220 common polymorphisms which can establish or refute sample identity among plasma, white blood cell and tumor samples. The genotype at each polymorphic location was identified, and the percent concordance between the samples of interest was calculated. Concordance was defined as the number of matched polymorphic sites that were identical in both samples divided by the total number of genotypes that had adequate coverage in both samples. Two samples were considered a match if concordance was > 0.99 and at least 5,000 amplicons had adequate coverage.

Statistical analysis

Continuous variables were reported as means and standard deviations or medians and range as deemed necessary while categorical variables were reported as whole numbers and percentages. Confidence intervals (CI) for sensitivities were calculated using a binomial

distribution. P-values were calculated with a one sided binomial test using the R *stats* package (version 3.3.1).

Results

[978] To identify a panel of protein and gene markers that might be used to detect many solid tumors at a stage prior to the emergence of distant metastases, a PCR-based assay was designing that could simultaneously assess multiple regions of driver genes that are commonly mutated in a variety of cancer types. Four challenges confronted this design. First, the test must query a sufficient number of bases to allow a large number of cancers to be detected. Second, each queried base must be sequenced thousands of times to detect mutations present at low prevalence. Third, the more bases that are queried the more likely that artifactual mutations will be identified, reducing the signal-to-noise ratio. And fourth, a test that can be implemented in a screening setting must be cost effective and high throughput, limiting the amount of sequencing that must be performed. To meet these contrasting challenges, a minimum number of short amplicons was identified that would allow detection of at least one driver gene in each of the eight tumor types evaluated. Using Publicly available sequencing data was used to determine that there was a fractional power law relationship between the number of amplicons required and the sensitivity of detection, with a plateau at ~ 60 amplicons (Fig. 2). Raising the number of amplicons above a threshold level would not detect substantially more cancers but would increase the probability of false positive results. This decreasing marginal utility defined the optimal number of amplicons.

[979] Based on these data, a 61-amplicon panel was designed with each amplicon querying an average of 33 bp within one of 16 genes (see Materials and Methods). As shown in Fig. 2, this panel would theoretically detect 41% (liver) to 95% (pancreas) of the cancers in the Catalog of Somatic Mutations in Cancer (COSMIC) dataset (Forbes *et al.*, 2017 *Nucleic Acids Res* 45:D777-D783). In practice, the panel performed considerably better, detecting at least one mutation in 82%, two mutations in 47%, and more than two mutations in 8% of the 805 cancers evaluated in our study (dots in Fig. 2, Fig. 3, and Table 1). A larger fraction of tumors was detected than predicted by the COSMIC dataset because the PCR-based

sequencing assay was more sensitive for detecting mutations than conventional genome-wide sequencing. Based on this analysis of the DNA from primary tumor tissues, the predicted maximum detection capability of circulating tumor DNA (ctDNA) varied by tumor type, ranging from 60% for liver cancers to 100% for ovarian cancers (Fig. 2).

[980] Armed with this small but robust panel of amplicons, two approaches were developed that enabled the detection of the rare mutations expected to be present in plasma. First, a multiplex-PCR was used to directly and uniquely label each original template molecule with a DNA barcode. This design minimized the errors inherent to massively parallel sequencing and made efficient use of the small amount of cell-free DNA present in plasma. Additionally, the total amount of DNA recovered from plasma was divided into multiple aliquots and independent assays were performed on each replicate. This decreased the number of DNA molecules per well; however, it increased the fraction of each mutant molecule per well making it easier to assay. Because the sensitivity of detection is often limited by the fraction of mutant alleles in each replicate, this partitioning strategy allowed an increase in the signal-to-noise ratio and identification of mutations present at lower prevalence than possible if all of the plasma DNA was evaluated at once.

[981] The second component of CancerSEEK is based on protein biomarkers. The literature was searched to find proteins potentially useful for early detection and cancer diagnosis in at least one of the eight cancer types described above with sensitivities > 10% and specificities > 99%. 41 potential protein biomarkers were identified and evaluated in preliminary studies on plasma samples from individuals without cancer and from cancer patients. 39 of these proteins could be reproducibly evaluated through a single immunoassay platform and these were then used to assay all plasma samples. Ten of these 39 proteins proved to be useful for discriminating cancer patients from healthy controls, and are set forth below.

Protein biomarkers analyzed and included in exemplary CancerSEEK test.

[982] This study included 1,005 patients with Stage I to III cancers of the ovary, liver, esophagus, pancreas, stomach, colorectum, lung, or breast. No patient received neo-adjuvant chemotherapy prior to blood sample collection. None had evident distant metastasis at the time of study entry and all underwent surgical resection with the intent to cure. The median age at diagnosis was 64 (range 22 to 93). The eight cancer types were chosen because they are common and because no blood-based tests for earlier detection of them are in common clinical use. The histopathological and clinical characteristics of the patients are summarized in Table 2.

[983] The most common stage at presentation was American Joint Commission on Cancer (AJCC) stage II, accounting for 49% of patients, with the remaining patients harboring stage I (20%), or stage III (31%) disease. The number of samples per stage for each of the eight tumor types is summarized below. A total of 812 individuals of median age 55 (range 17 to 88) with no known history of cancer, high-grade dysplasia, autoimmune disease, or chronic kidney disease acted as the healthy control cohort.

Cancer patients evaluated in this study by tumor type and stage.

Tumor Type	AJCC Stage	Patients (n)	Proportion of cases (%)
Breast	I	32	15
	II	114	55
	III	63	30
	I-III	209	--
Colorectum	I	77	20
	II	191	49

[984] CancerSEEK evaluates levels of 10 proteins and mutations in 2,001 genomic positions; each genomic position could be mutated in several ways (single base substitutions, insertions, or deletions). The presence of a mutation in an assayed gene or an elevation in the level of any of these proteins would classify a patient as positive. Rigorous statistical methods were employed to ensure the accuracy of the test. Log ratios were used to evaluate mutations and incorporated them into a logistic regression algorithm that took into account both mutation data and protein biomarker levels to score CancerSEEK test results. The mean sensitivities and specificities were determined by ten iterations of 10-fold cross-validations. The receiver operating characteristic (ROC) curves for the entire cohort of cancer patients and controls in one representative iteration is shown in Fig. 4A.

[985] The median sensitivity of CancerSEEK among the eight cancer types evaluated was 70% ($p < 10^{-96}$ one-sided binomial test) and ranged from 98% in liver cancers to 33% in breast cancers (Fig. 4C). At this sensitivity, the specificity was > 99%, i.e., only 6 of the individuals without known cancers scored positive.

[986] The features of the test that were most important to the algorithm were the presence of a ctDNA mutation followed by elevations of Prolactin, OPN, IL-6, CEA, CA125, HGF, Myeloperoxidase, CA19-9, Midkine, and TIMP-1 protein levels. Waterfall plots for each of the ctDNA and protein features used in CancerSEEK illustrate their distribution among individuals with and without cancer (Fig. 4). The importance ranking of the ctDNA and protein features used in CancerSEEK are provided below and a principal component analysis displaying the clustering of individuals with and without cancer is shown in Fig. 5. The complete dataset, including the levels of all proteins studied and the mutations identified in the plasma samples, are provided in Table 3 and Table 4. The probabilistic rather than deterministic nature of the approach used here to call a sample positive is evident from Fig. 6; each panel represents the sensitivity of CancerSEEK when one specific feature was excluded from the analysis.

[987] A screening test is advantageously able to detect cancers at early stages. The median sensitivity of CancerSEEK was 73% for the most common stage evaluated (Stage II), similar (78%) for Stage III cancers, and lower (43%) for Stage I cancers (Fig. 4B). The sensitivities for the earliest stage cancers (Stage I) were highest for liver (100%) and lowest for esophageal cancer (20%).

[988] The basis of liquid biopsy is that mutant DNA templates in plasma are derived from dying cancer cells and thus serve as exquisitely specific markers for neoplasia. To test this expectation, tumor tissue from 155 patients in whom ctDNA could be detected at statistically significant levels and in whom primary tumors were available were evaluated. The mutation in the plasma was identical to a mutation found in the primary tumor of the same individual in 138 (90%) of these 155 cases (Table 5). This concordance between plasma and primary tumor was evident in all 8 cancer types, and ranged from 100% in ovarian and pancreatic cancers to 82% in stomach cancers.

[989] A major limitation of conventional liquid biopsies is their inability to determine the cancer type in patients who test positive, thereby posing challenges for clinical follow-up. In addition to increasing the sensitivity of detection, the combination of protein biomarkers and ctDNA helped identify the type of cancer that might exist with a positive CancerSEEK test. Supervised machine learning was used to predict the underlying cancer type in patients with

positive CancerSEEK tests. The input algorithm took into account the gender of the patient and the protein and ctDNA biomarker data. One of the main purposes of such predictions is to determine the most appropriate follow up test for cancer diagnosis or monitoring after a positive CancerSEEK test. Patients with esophageal and gastric cancers were grouped together, as the optimal follow-up for individuals potentially affected with these two cancers would be endoscopy.

[990] An algorithm was used to study the 617 patients scoring positive in the CancerSEEK Test. Without any clinical information about the patients, the source of the cancer was localized to two anatomic sites in a median of 83% of these patients (Fig. 8, Table 6; $p < 10^{-77}$ one-sided binomial test). Furthermore, the source of the positive test was localized to a single organ in a median of 63% these patients (Fig. 8, Table 6; $p < 10^{-47}$ one-sided binomial test). The accuracy of prediction varied with tumor type and was best for colorectal cancers and lowest for lung cancers as shown below (see, also, Fig. 8).

Confusion matrix of top predictions from cancer type localization results.

		Breast	Colorectum	Liver	Lung	Ovary	Pancreas	Upper GI
Predicted cancer type	**Breast**	63%	3%	2%	8%	4%	3%	3%
	Colorectum	26%	84%	30%	48%	15%	15%	44%
	Liver	0%	1%	44%	2%	0%	0%	4%
	Lung	4%	2%	0%	39%	2%	1%	4%
	Ovary	3%	0%	0%	2%	79%	0%	0%
	Pancreas	4%	2%	9%	2%	0%	81%	0%
	Upper GI	0%	9%	14%	0%	0%	0%	46%

[991] The results described herein demonstrate that a blood test based on genes and proteins can be used to detect a major fraction (median of 70%) of eight major cancer types. In the majority of the samples that scored positive, the underlying cancer type could be predicted simply from the test results without any prior knowledge of the patient's medical history or disease status. The specificity of CancerSEEK was high, with less than 1% of 812 individuals without known cancers scoring positive.

Example 2: Combination approach to liquid biopsy cancer screening tests with increased sensitivity and high specificity

[992] There is a strong correlation between tumor stage and prognosis in many cancers (see, e.g., Ansari et al., 2017 *Br J Surg* 104(5):600-607). Very few patients with cancers of the lung, colon, esophagus, or stomach who have distant metastasis at the time of diagnosis survive for more than five years (see, e.g., Howlader et al., 2016 SEER Cancer Statistics Review, 1975-2013, National Cancer Institute. Bethesda, MD). It is therefore evident that earlier detection of cancers is one key to reducing deaths from these diseases.

[993] Biomarkers in the circulation provide one of the best ways, in principle, to detect cancers at an earlier stage. Historically, the type of biomarkers used to monitor cancers were proteins (see, e.g., Liotta et al., 2003 *Clin Adv Hematol Oncol* 1(8):460-462). More recently, mutant DNA has been explored as a biomarker as DNA released from the dying cells can escape into bodily fluids such as urine, stool, and plasma (see, e.g., Haber et al., 2014 *Cancer Discov* 4(6):650-661; Dawson et al., 2013 *N Engl J Med* 368(13):1199-1209; Bettegowda et al., 2014 *Science translational medicine* 6(224):224ra224; Kinde et al., 2013 *Science translational medicine* 5(167):167ra164; Wang et al., 2015 *Science translational medicine* 7(293):293ra104; Wang et al., 2015 *Proc Natl Acad Sci U S A* 112(31):9704-9709; Wang et al., 2016 *Elife* 5; Springer et al., 2015 *Gastroenterology* 149(6):1501-1510; Forshew et al., 2012 *Science translational medicine* 4(136):136ra168; Vogelstein et al., 1999 *Proc Natl Acad Sci U S A* 96(16):9236-9241; and Dressman et al., 2003 *Proc Natl Acad Sci U S A* 100(15):8817-8822). The concept underlying this approach, often called "liquid biopsies" is that cancer cells, like normal self-renewing cells, turn over frequently. However, studies of circulating tumor DNA (ctDNA) indicate that while ctDNA is elevated in >85% of patients with advanced forms of many cancer types, a considerably smaller fraction of patients with earlier stages of cancer have detectable levels of ctDNA in their plasma (see, e.g., Bettegowda et al., 2014 *Science translational medicine* 6(224):224ra224; and Wang et al., 2015 *Science translational medicine* 7(293):293ra104).

[994] This Example describes using a combination approach to cancer screening tests which increases the sensitivity of detection of resectable or otherwise treatable cancers under

conditions that preserve high specificity. For example, the assays described in this Example combine detection of mutations in ctDNA with detection of threshold protein markers in plasma.

Materials and Methods

Plasma, white blood cell and tumor DNA samples

[995] DNA was purified from plasma using a QIASymphony circulating DNA kit (Qiagen, cat # 1091063). Custom primers containing a unique identifier (UID) and amplicon specific sequences (Table 38) were used to amplify plasma DNA, and the resulting products were sequenced on an Illumina MiSeq or HiSeq instrument. Protein biomarker plasma concentrations were determined using Luminex bead based immunoassays on the Bioplex 200 platform (Biorad, Hercules CA). Plasma samples were scored as positive if the sample contained a KRAS mutation or if the concentration of CA19-9, CEA, HGF, or OPN was greater than 100 U/mL, 7.5 ng/mL, 0.92 ng/mL, or 158 ng/mL, respectively. All samples were obtained following approval by the Institutional Review Boards for Human Research at each institution and informed consent.

[996] Samples were obtained following approval by the Institutional Review Boards for Human Research at each institution and informed consent. Patients with Stage IA, IB, IIA or IIB (considered resectable) who had had peripheral blood collected prior to surgery, had not received neoadjuvant therapy, and had undergone surgical resection at the participating institutions between April 2011 and May 2016 were included in the study. General demographics, surgical pathology, and AJCC stage (7th edition) were documented. The 'healthy' cohort consisted of peripheral blood samples obtained from 185 individuals of average age 64 with no history of cancer. The pancreatic cancer and healthy control samples were collected and processed in an identical manner.

[997] DNA was purified from 3.75 mL plasma using a QIASymphony circulating DNA kit (cat # 1091063), as specified by the manufacturer. Tumor tissues were formalin-fixed and paraffin embedded (FFPE) according to standard histopathologic procedures and macro-dissected under a microscope to ensure a neoplastic cellularity of >30%. DNA was purified

with a QIAsymphony DP DNA Midi Kit (Cat # 937255) as specified by the manufacturer. DNA concentrations were assessed by fluorescence using SYBR Green I (Thermo Cat # S7585).

Mutation detection and analysis

[998] For amplification of DNA from plasma, primer pairs were designed to amplify 66 to 80 bp segments containing regions of interest from the KRAS and TP53 genes (Table 11 and Table 12). These primers were used to amplify DNA in six independent 25 µl reactions as described elsewhere (see, e.g., Wang et al., 2015 *Proc Natl Acad Sci U S A* 112(31):9704-9709). Reactions were purified with AMPure XP beds (Beckman Coulter, PA, USA) and eluted in 50 µl of Buffer EB (Qiagen). A fraction (5 µl) of purified PCR products were then amplified in a second round of PCR, as described elsewhere (see, e.g., Wang et al., 2015 *Proc Natl Acad Sci U S A* 112(31):9704-9709). The PCR products were purified with AMPure and sequenced on an Illumina MiSeq or HiSeq 4000 instrument.

[999] The template-specific portion of the reads was matched to reference sequences using custom scripts written in SQL and C#. Reads from a common template molecule were then grouped based on the unique identifier sequences (UIDs) that were incorporated as molecular barcodes (see, e.g., Allen et al., 2017 *Ann Surg* 265(1):185-191). Artefactual mutations introduced during the sample preparation or sequencing steps were reduced by requiring a mutation to be present in >90% of reads in each UID family.

Evaluation of plasma proteins

[1000] The Bioplex 200 platform (Biorad, Hercules CA) was used to determine the concentration of multiple target proteins in the plasma samples. Luminex bead based immunoassays were performed following the manufacturers protocols and concentrations were determined using 5 parameter log curve fits (using Bioplex Manager 6.0) with vendor provided standards and quality controls. Plasma samples were diluted 6-fold for assay of CA19-9, CEA, HGF, OPN and prolactin and 5-fold for assay of midkine. Plasma samples

were scored as positive if the concentration of CA19-9, CEA, HGF, or OPN was greater than 100 U/mL, 7.5 ng/mL, 0.92 ng/mL, or 158 ng/mL, respectively. The dynamic ranges of these immunoassays for CA19-9, CEA, HGF, OPN, prolactin, and midkine were 2.74 - 2,000 U/mL, 78.19 - 57,000 pg/mL, 27.43 - 20,000 pg/mL, 548.7 - 400,000 pg/mL, 137.17 - 100,000 pg/mL, and 13.72 - 10,000 pg/mL, respectively.

Algorithm for classifying ctDNA status

[1001] The classification of a sample's ctDNA status was obtained from a statistical test comparing the normalized mutation frequencies of the sample of interest to a distribution of normal controls. Specifically, the MAF, defined as the ratio between the number of supermutants and the number of UIDs, was first normalized based on the observed MAFs in a set of normal controls for each mutation. Following this mutation-specific normalization, the MAF of each mutation in each well was compared to a reference distribution of MAFs built from normal controls with all mutations included, and a p-value was calculated from this distribution. The lowest p-value among all mutations detected in a given sample was deemed the "top mutation". The classification of a sample's ctDNA status was based on whether the p-value of this top mutation was below or above a given threshold. The threshold was selected based on a desired specificity observed among an independent set of normal controls. Thus, no training was performed on any other sample except these controls; in particular, neither the 182 healthy controls nor the 221 pancreatic cancer patients described in the main text were included in the controls used for training the algorithm.

Statistical analysis

[1002] Continuous variables were reported as means and standard deviations or medians and range as deemed necessary while categorical variables were reported as whole numbers and percentages. Confidence intervals (CI) for sensitivities were calculated using a binomial distribution. Survival curves were estimated using Kaplan-Meier method and differences between curves were investigated with the log-rank test. Statistically significant variables in

the univariate analyses were subjected to multivariable Cox proportional hazard regression model.

[1003] Hazard ratio (HR) and 95% confidence interval (CI) for variables included in the multivariable model were reported. A p-value < 0.05 was considered to be statistically significant.

Results

Characteristics of patients with PDAC and presumed healthy controls

[1004] Two hundred and twenty-one patients with surgically resectable pancreatic cancer were evaluated in this study. The histopathological and clinical characteristics of these patients are summarized in Table 7. A total of 182 individuals of similar age with no known history of cancer, autoimmune disease, or chronic kidney disease acted as the healthy control cohort.

[1005] Twenty percent of the patients had no symptoms typically associated with pancreatic cancer. The size of the primary tumors at presentation ranged from 0.6 cm to 13 cm, with a median size of 3.0 cm. The most common stage at presentation was American Joint Commission on cancer stage (AJCC) Stage IIB, accounting for 77% of patients, with the remaining patients harboring Stage IA (5%), Stage IB (8%) or Stage IIA (10%) (Table 7). Patient survival correlated with stage, as graphically depicted in Fig. 12 and as expected from prior clinical studies (see, e.g., Allen et al., 2017 *Ann Surg* 265(1):185-191).

PCR-based assay to identify tumor-specific KRAS mutations in plasma samples

[1006] A PCR-based assay was designed that could simultaneously assess the two codons (codons 12 and 61) of the KRAS gene that are most frequently mutated in PDAC as well as surrounding codons. The assay employed a sensitive technology called the Safe-Sequencing System (Safe-SeqS) (see, e.g., Kinde et al., 2011 *Proc Natl Acad Sci U S A* 108(23):9530-9535). Safe-SeqS incorporates molecular barcodes that uniquely label each template molecule, thereby drastically minimizing the errors that routinely occur in massively parallel

sequencing. This approach can identify one mutant template among as many as 10,000 normal templates. Using this technology, KRAS mutations in the plasma of 66 of the 221 (30%: 95% CI 24—36%) pancreatic cancer cases (see below, and Table 8) were identified. Sixty-two (94%) and four (6%) of the mutations were at codons 12, and 61, respectively, with G>T transversions most commonly observed (Table 8). Mutations were found more frequently in Stage II patients than in Stage I patients (see below, Table 8, and Fig. 9A). Additionally, while the mutant allele frequency did not correlate with tumor size (Table 8, and Fig. 11A), mutations were found more frequently in larger tumors than in smaller tumors (see below, Table 8, and Fig. 9B).

Proportion of samples stratified by AJCC stage detected with each individual assay and all combinations thereof.

	Proportion of samples detected (95% confidence interval)				
Assay Type	Stage IA (12 cases)	Stage IB (17 cases)	Stage IIA (22 cases)	Stage IIB (170 cases)	Stage I&II (221 cases)
KRAS ctDNA	25% (5-57%)	0% (0-20%)	18% (5-40%)	35% (28-42%)	30% (24-36%)
CA19-9	17% (2-48%)	41% (18-67%)	36% (17-59%)	54% (46-62%)	49% (43-56%)
CEA + HGF + OPN	25% (5-57%)	6% (0-29%)	14% (3-35%)	19% (14-26%)	18% (13-24%)
KRAS ctDNA + CA19-9	33% (10-65%)	41% (18-67%)	50% (28-72%)	65% (58-72%)	60% (53-67%)
KRAS ctDNA Mutations + CEA + HGF + OPN	33% (10-65%)	6% (0-29%)	32% (14-55%)	47% (39-55%)	42% (35-48%)
CA19-9 + CEA + HGF + OPN	25% (5-57%)	47% (23-72%)	36% (17-59%)	59% (52-67%)	54% (47-61%)
Combination Assay	33% (10-65%)	47% (23-72%)	50% (28-72%)	69% (62-76%)	64% (57-70%)

Proportion of samples stratified by tumor size detected with each individual assay and all combinations thereof.

[1007] The number of mutant templates in the plasma could be calculated from the mutant allele fraction and the concentration of DNA in each plasma sample (Table 8). This number was often very low, with 15 (23%) of the patients with detectable KRAS mutations having < 2 mutant templates per ml of plasma. The average number of mutant templates per mL of plasma was 9.4 (Table 8). These results emphasize that extremely sensitive techniques can be used to detect the mutations in early stage pancreatic cancer patients. KRAS mutations were only observed in one of the 221 individuals in the presumed healthy cohort, a 69-year-old male with no known cancer.

[1008] The basis for the liquid biopsy concept is that the mutant DNA templates identified in the circulation are derived from cancers. It was therefore important to determine whether the KRAS mutations identified in these patients' plasma samples were also present in their primary carcinomas. Primary carcinomas from 50 of the 66 patients with detectable KRAS mutations in their plasma were obtained. In all 50 cases, the mutation found in the plasma was identical to that found in the primary carcinoma, providing another, orthogonal measure of specificity.

Simultaneous assessment of CA19-9 and KRAS mutations in plasma

[1009] It was sought to determine whether a combination of the KRAS ctDNA test with CA19-9, the PDAC biomarker, would result in improved sensitivity compared with the KRAS ctDNA test alone. Recent studies have shown that CA19-9 can be elevated in patients with pancreatic cancer two years prior to diagnosis (see, e.g., O'Brien et al., 2015 *Clin Cancer Res* 21(3):622-631). However, CA19-9 elevations have also been observed in non-malignant conditions, and 5% of the population cannot produce the CA19-9 antigen due to germline genetic variation, limiting its use for screening purposes (see, e.g., Lennon et al., 2010 Diagnostic and Therapeutic Response Markers. *Pancreatic Cancer*, (Springer New York, New York, NY), pp 675-701). However, it was reasoned that CA19-9 might prove useful as a screening biomarker if the threshold for scoring a result as positive was sufficiently high. A threshold of 100 U/mL was chosen based on prior data that this level is

not found among healthy individuals who do not have a clinical history of pancreaticobiliary disease (see, Kim et al., 2004 *J Gastroenterol Hepatol* 19(2):182-186).

[1010] Using this predefined high threshold, CA19-9 was detected in 109 of the 221 (49%: 95% CI 43—56%) patients with pancreatic cancer, and in none of the 182 healthy controls, confirming its specificity when used in this way (Table 8, and Table 9). As expected, the number of patients with detectable CA19-9 levels increased with stage and tumor size (Fig. 9, and Table 8). A question addressed in the current study was whether these two biomarkers – KRAS mutations and a positive CA19-9 score – were independent indicators of the presence of disease. It was found that the overlap was only partial, as indicated in the Venn diagram in Fig. 10. Though 42 patients (19%) had elevated CA19-9 levels as well as detectable KRAS mutations in their plasma, 91 additional patients had either mutations in KRAS or elevated CA19-9, but not both (Fig. 10). Thus, the combined sensitivity of these analyses was 60% (95% CI 53—67%), higher than the sensitivity of either alone (Fig. 9). As such, this Example demonstrates that the two assays could be combined without substantially increasing the false positive rate because each was extremely specific at the thresholds used.

Increasing sensitivity by inclusion of other protein biomarkers

[1011] Encouraged by the results described above, it was sought to further increase sensitivity by combining ctDNA KRAS mutations and CA19-9 with other protein biomarkers (Table 10). In a pilot study on a small number of pancreatic cancer samples independent from those studied here, the potential utility of other proteins that had been found to be elevated in cancer, including alpha-fetoprotein (AFP), CA15-3, leptin, IL-6, carcinoembryonic antigen (CEA), CA-125, interleukin 8 (IL-8), sFas, prolactin, osteopontin (OPN), basic fibroblast growth factor (FGF2), hepatocyte growth factor (HGF), cytokeratin-19 fragment (CYFRA 21-1), human epididymis protein 4 (HE4), transforming growth factor alpha (TGF-α), growth/differentiation factor 15 (GDF15), dickkopf-related protein 1 (DKK1), neuron specific enolase (NSE), osteoprotegerin (OPG), TIMP metallopeptidase inhibitor 1 (TIMP-1), TIMP metallopeptidase inhibitor 2 (TIMP-2), mesothelin, midkine, kallikrein-6, CD44, AXL receptor tyrosine kinase, soluble human epidermal growth factor receptor 2 (sHER2),

soluble epidermal growth factor receptor (sEGFR), soluble urokinase-type plasminogen activator receptor (suPAR), and soluble platelet endothelial cell adhesion molecule (sPECAM-1) was evaluated. Of these 29 protein biomarkers, five—CEA (see, e.g., Nazli et al., 2000 *Hepatogastroenterology* 47(36):1750-1752), HGF (see, e.g., Di Renzo et al., 1995 *Cancer Res* 55(5):1129-1138), midkine (see, e.g., Ikematsu et al., 2000 *Br J Cancer* 83(6):701-706), OPN (see, e.g., Koopmann et al., 2004 *Cancer Epidemiol Biomarkers Prev* 13(3):487-491), and prolactin (see, e.g., Levina et al., 2009 *Cancer Res* 69(12):5226-5233)—were chosen for further analysis.

[1012] When the levels of these five markers were evaluated in plasmas from the 221 patient pancreatic cancer cohort, an association between the plasma concentrations of prolactin and midkine and surgical site ($P < 0.01$, $\chi 2$ test, degrees of freedom = 5) was observed, suggesting that blood collection conditions might have elevated the levels of these two markers. There was no significant correlation between CA19-9, CEA, HGF, or OPN levels and collection sites, nor was there any correlation between the presence of KRAS ctDNA mutations and collection site ($P > 0.01$, $\chi 2$ test, degrees of freedom = 5). Upon further investigation, it was noted that the levels of prolactin and midkine were significantly elevated in samples that were collected after the administration of anesthesia but before surgical excision (Fig. 14). The results on prolactin were consistent with previous studies showing that anesthetics elevate the levels of this protein (see, e.g., Thorpe et al., 2007 *PLoS One* 2(12):e1281). To ensure that anesthesia did not affect the levels of the other protein biomarkers described above, paired plasma samples were collected before and immediately after the administration of anesthesia in 29 new patients. The only proteins found to be elevated by anesthesia were prolactin and midkine (Fig. 15), in perfect accordance with the correlation between collection site and protein levels noted above. Prolactin and midkine were therefore excluded from further analysis.

[1013] Unlike CA19-9, no predefined threshold exists for the use of CEA, HGF, or OPN as markers for pancreatic cancer. As a result, appropriate thresholds were determined in an independent set of 273 plasma samples from healthy controls. To be conservative, thresholds for each protein that were 10% higher than the maximum values observed in any of the 273 normal plasma samples were chosen. Notably, when these thresholds were applied to the

independent test set of 182 plasma samples, all three protein markers maintained 100% specificity (Table 9). The sensitivity of each of these three markers was less than that obtained with KRAS mutations or CA19-9 when each marker was used alone, but their levels were less dependent on stage and size than KRAS mutations or CA19-9 (Fig. 13, and Table 8). In combination with KRAS mutations and CA19-9 assays, this five-member biomarker panel ("combination assay") detected 141 (64%: 95% CI 57—70%) of the 221 resectable cancers (Table 7, Fig. 9A, Fig. 10, and Table 8).

[1014] Some of the patients detectable by the combination assay were of particular note. Forty-five (20%) patients had no symptoms classically associated with pancreatic cancer (Table 8). The combination assay identified 27 (60%) of these individuals, of whom 19 (70%) had no evidence of recurrence with a median follow up of 12 (range 3 – 16) months (Table 8). Of the 29 patients with the earliest stages of disease (Stages IA and IB) recognized by the AJCC, 12 (41%) were detectable using the combination assay (Fig. 9A), of whom 7 (58%) had no evidence of recurrence at the study termination with a median follow up of 19 (range 2 – 25) months.

[1015] Another notable but sobering result from this study was that patients with poorer survival were more likely to have a positive test. Of the entire 221 pancreatic cancer patients studied, 122 (56%) patients were alive at the termination of the study, with a median follow-up of 13 (7 – 21) months. It was found that the combination assay provided prognostic value that was independent of conventional clinical and histopathologic features. In particular, multivariate analyses showed that the independent predictors of overall survival were combination assay status (HR = 1.76, 95% CI, 1.10–2.84, p = 0.018), increasing age (HR = 1.04, 95% CI 1.02-1.06, p = 0.001), grade of differentiation (poorly differentiated, HR = 1.72, 95% CI 1.11–2.66, p = 0.015), lymphovascular invasion (present, HR = 1.81, 95% CI 1.06 – 3.09, p = 0.028), nodal disease (present, HR = 2.35, 95% CI 1.20 – 4.61, p = 0.013), and margin status (HR = 1.59, 95% CI 1.01 – 2.55, p = 0.050) (Table 7, Fig. 16).

TP53 in a multiplex assay

[1016] While nearly all pancreatic cancers harbor mutations within KRAS, a large fraction (~75%) also contains mutations in TP53 (see, e.g., Jones et al., 2008 *Science* 321(5897):1801-1806; Biankin et al., 2012 Nature 491(7424):399-405; and Waddell et al., 2015 *Nature* 518(7540):495-501). Furthermore, TP53 is the mostly commonly mutated gene in cancer (see, e.g., Vogelstein et al., 2013 *Science* 339(6127):1546-1558), making it an attractive target for ctDNA detection in future studies involving other tumor types. To determine whether the mutant allele frequencies of TP53 in the plasma correlated with those of KRAS, and also to determine whether a mutant TP53 assay in plasma might add to the sensitivity of the mutant KRAS assay, the 152 carcinomas for which matched tumor and plasma samples were available were evaluated. Mutations at one of the "hotspots" identified in genome-wide studies of PDAC (see, e.g., Jones et al., 2008 *Science* 321(5897):1801-1806) were first searched for. A total of 64 (42%) carcinomas contained a TP53 mutation at one of these positions. It was then determined whether these same mutations could be identified in the plasma of these 64 patients, using Safe-SeqS-based assays similar to that described above for KRAS but using primers specific for particular TP53 mutations.

[1017] TP53 mutations in 13 (20%) of the 64 plasma samples (see below) were identified. Two observations were of interest. First, 12 of the 13 plasma samples containing a detectable TP53 mutation also contained a detectable KRAS mutation. Thus, TP53 mutation assays did not substantially increase sensitivity for pancreatic cancer detection, as expected from the high prevalence of KRAS mutations noted above. Second, there was a strong correlation between the mutant allele frequencies of TP53 and KRAS mutations in the plasma of the 12 patients whose plasma contained detectable amounts of both mutations (Fig. 3, Pearson's r = 0.885). This provides yet another validation of the reliability of the ctDNA assay and its quantitative nature.

List of exemplary TP53 mutations detected in PDAC patients

Example 3: Sensitivity and specificity of ctDNA and protein biomarkers

Materials and Methods

Phase A

[1018] Healthy Cohort: Ten thousand non-symptomatic women are recruited. The age range of participants is 65 to 75 years, as this range captures patients at maximum risk for cancers of the eight types that are the target of detection. Women with oophorectomies, known cancer of any type other than non-melanoma skin cancer, are excluded from the study. Plasma from each participant is obtained at study entry. In participants who test positive, as well as in a random sample of participants with negative tests, one additional sample of plasma is drawn at 3 months following the first test. When both tests are positive for the same mutation, a whole body PET/CT scan is performed. If the PET/CT exam is positive, patients are managed as deemed appropriate by their physicians. This management includes yearly follow-up ctDNA tests. Yearly follow-up of patients via electronic questionnaires, combined with phone interviews when necessary, are obtained on all individuals, whether their tests are positive or negative.

[1019] Management Cohorts: Two hundred patients with Stage III colon cancers and 50 patients with resectable pancreatic cancers are recruited from at least 10 sites across Australia, New Zealand and Singapore. Tumor samples are tested to identify mutations that can be used for subsequent ctDNA tests. Plasma samples are collected on all patients prior to surgery (including those randomized to receive routine care). Additional plasma samples are collected at 3, 6, and 12 months in patients whose ctDNA tests are positive prior to surgery. No further ctDNA analyses are performed in ctDNA-negative patients or those randomized to receive routine care. Patients are randomized 1:1 to ctDNA-informed management (with treatment escalation or de-escalation compared to standard of care, or to routine care [blinded to ctDNA test results]).

Phase B

[1020] Healthy Cohort: Forty thousand more non-symptomatic women are recruited. The inclusion and exclusion criteria are the same as in Phase A. Other than the longer follow-up and larger number of patients, there are at least two other differences between Phase A and Phase B. First, protein biomarkers that passed the specificity threshold (>99.5%) in Phase A samples are included. Patients who test positive for one or more of these protein biomarkers are managed identically to those with positive ctDNA results. Second, a "control" Healthy Cohort is added. These represents individuals recruited from the same population but in whom no blood samples are taken to assess disease or guide management. These controls are used to assess the ability of the screening tests to detect disease before they would ordinarily be detected on the basis of symptoms or standard medical care of healthy individuals. Comparisons between stage and survival in the screened and control cohorts are also made.

[1021] Management Cohorts: One thousand more patients with Stage III colon cancers (a total of 1200 patients) and 210 more patients with resectable pancreatic cancers (for a total of 250 patients) are recruited, but now at 30 sites rather than 10 sites. Similarly, to Phase A, tumor samples are collected at surgery in all new patients and mutations identified so that they can be used in subsequent ctDNA tests. Additionally, protein biomarkers for colorectal or pancreatic cancers that passed the specificity threshold (>99.5%) in Phase A are included. Patients who test positive for these protein biomarkers are managed identically to those with positive ctDNA results. Plasma samples are collected on all patients prior to surgery and at 3, 6, and 12 months in patients whose ctDNA tests are positive prior to surgery. Patients are randomized 1:1 to ctDNA-informed management (with treatment escalation or de-escalation compared to standard of care, or to routine care [blinded to ctDNA result]).

Evaluations

[1022] The Safe-SeqS-based ctDNA test that is used in the Healthy Cohort incorporates 61 amplicons representing the most commonly mutated regions of cancer driver genes. It is

estimated that ~70% of the eight cancer types to be targeted have mutations in at least one of the regions covered by these amplicons. The fraction of plasmas that have mutations in at least one of these amplicons is less than 70% because not all cancers give rise to ctDNA (see Bettegowda et al., Sci Transl Med. 2014 Feb 19;6(224):224ra24. doi: 10.1126/scitranslmed.3007094.).

[1023] For the Management Cohort, a targeted sequencing assay is first used to identify at least one mutation in the FFPE-cancer obtained from surgery or biopsy. This Safe-SeqS-based test employs 128 amplicons and we have used it to detect at least one pathogenic driver gene mutation in 395 of 401 colorectal cancers and in 200 of 200 pancreatic cancers tested. One specific amplicon that detects a mutation in each individual patient's tumor is then used to evaluate the plasma from that patient at the specified time points – in other words, a fully personalized assay.

[1024] In addition to the tests on circulating tumor DNA (ctDNA), a panel of ~25 protein biomarkers is assessed using a Luminex platform on a subset of plasma samples from the Healthy Cohort. The assays for these proteins have been well-established. If the thresholds for positivity are set to a high level, they provide additional information that can be combined with the ctDNA test results to improve sensitivity without compromising specificity. Markers that exhibit >99.5% specificity in Phase A are incorporated into Phase B of the study.

Example 4: Detecting gynecologic malignancies using a combination approach cancer screening tests

[1025] Diagnosis of gynecologic malignancy (e.g., cervical cancers, ovarian cancers, and endometrial cancers) often includes the Papanicolaou (Pap) test, transvaginal ultrasound (TVUS), and/or detection of the CA-25 biomarker. However, screening with current diagnostic approaches is not recommended for the general population, as it leads to "important harms, including major surgical interventions in women who do not have cancer" (see, e.g., Moyer, 2012 *Annals of internal medicine* 157:900-904). Thus, new diagnostic approaches are urgently needed.

[1026] This Example describes a new blood test, called PapSEEK, which addresses the problematic issues described above. In this test, DNA from sampled fluid (e.g., fluid containing cells sampled from the endocervical canal) can be used in an assay (e.g., a PCR-based, multiplex test) to simultaneously assess genetic alterations that commonly occur in endometrial or ovarian cancers (Fig. 19). Overall, 1915 samples from 1658 individuals were included in the studies described herein, including 656 patients with endometrial or ovarian cancers and 1002 healthy controls. The age, race, histopathologic diagnosis, stage and other clinical information for the cancer patients are provided in Table 13. The samples tested from these patients are listed in Table 14.

Materials and Methods

Patient Samples

[1027] All samples for this study were obtained according to protocols approved by the Institutional Review Boards of the Johns Hopkins Medical Institutions (Baltimore, MD), McGill University (Montreal, QC, Canada), Gothenburg University (Gothenburg, Sweden), BioreclamationIVT (Chestertown, MD), Memorial Sloan Kettering Cancer Center (New York City, NY), and the Danish Scientific Ethical Committee (Copenhagen, Denmark). Demographic, clinical, and pathologic staging data were collected for each patient with cancer are listed in Table 13. The average age of 714 women without cancer used for Pap brush analysis was 34 (range: 17 to 67 years). The average age of 125 women without cancer used for Tao brush analysis was 29 (range: 18 to 74 years). All histopathology was re-reviewed by board-certified pathologists. DNA was extracted from tumors, Pap smear fluid, and plasma as described elsewhere (see, e.g., Kinde et al., 2011 *Proc Natl Acad Sci U S A* 108:9530-9535; and Bettegowda et al., 2014 *Sci Transl Med* 6:224ra224). For intrauterine sampling, Tao Brush IUMC Endometrial Sampler (Cook Medical Inc., Bloomington, IN) was gently inserted to the level of the uterine fundus. The outer sheath was then pulled back and the brush was rotated 360 degrees clockwise and then counterclockwise. Then the outer sheath was pushed again and the device was removed. The sample was placed into Thin-Prep

buffer, from which DNA was purified using an AllPrep DNA kit (Qiagen, Germany) according to the manufacturer's instructions. Purified DNA from all samples was quantified as described elsewhere (see, e.g., Rago et al., 2007 *Cancer research* 67:9364-9370).

[1028] Healthy controls included patients with normal cytology findings on Pap smears and no history of gynecologic tumors. Ovarian cancer patients with history of tubal ligation were excluded from the study.

Somatic mutation detection and analysis

[1029] DNA from Pap smear fluid, Tao brush samples, or primary tumors was amplified in three multiplex PCR reactions consisting of 139 primer pairs that were designed to amplify 110 to 142 bp segments, as described elsewhere (see, e.g., Wang et al., 2016 *Elife* 5). These segments contain regions of interest from the following 18 genes: *AKT1*, *APC*, *BRAF*, *CDKN2A*, *CTNNB1*, *EGFR*, *FBXW7*, *FGFR2*, *KRAS*, *MAPK1*, *NRAS*, *PIK3CA*, *PIK3R1*, *POLE*, *PPP2R1A*, *PTEN*, *RNF43*, and *TP53*. For each sample, three multiplex reactions, each containing non-overlapping amplicons, were performed, as described elsewhere (see, e.g., Wang et al., 2016 *Elife* 5). Each sample was assessed in two duplicate wells. DNA from plasma was amplified in two multiplex PCR reactions consisting of 61 primer pairs that were designed to amplify 67 to 81 bp segments. Each sample was assessed in six duplicate wells. These segments contained regions of interest from the following genes: *AKT1, APC, BRAF, CDKN2A, CTNNB1, EGFR, FBXW7, FGFR2, GNAS, HRAS, KRAS, NRAS, PIK3CA, PPP2R1A, PTEN,* and *TP53*.

[1030] Safe-SeqS, an error-reduction technology for detection of low frequency mutations (see, e.g., Kinde et al., 2011 *Proc Natl Acad Sci U S A* 108:9530-9535), was used for all sequencing analyses. One primer in each pair included a unique identifier sequence (UIDs), consisting of 14 degenerate bases with an equal chance of being an A, C, T, or G. High quality sequence reads were selected based on quality scores, which were generated by the sequencing instrument to indicate the probability a base was called in error. Reads from a common template molecule were then grouped based on the UIDs that were incorporated as molecular barcodes. Artifactual mutations introduced during the sample preparation or

sequencing steps were reduced by requiring a mutation to be present in >90% of reads in each UID family (i.e., to be scored as a "supermutant") (see, e.g., Kinde et al., 2011 *Proc Natl Acad Sci U S A* 108:9530-9535).

Statistical analysis of sequencing data

[1031] All Pap brush and Tao brush samples were analyzed using a mutant allele fraction (MAF)-based approach. Mutations that met one of the two following criteria were considered (i) present in the COSMIC database (see, e.g., Forbes et al., 2017 *Nucleic Acids Res* 45:D777-D783), or (ii) predicted to be inactivating in tumor suppressor genes (nonsense mutations, out-of-frame insertions or deletions, canonical splice site mutations). Synonymous mutations, except those at exon ends (see, e.g., Jung et al., 2015 *Nat Genet* 47:1242-1248), and intronic mutations, except for those at splice sites, were excluded. The MAF in the sample of interest was first normalized based on the distribution of MAFs for the same mutation in the control group. Following this mutation-specific normalization, a p-value was obtained by comparing the MAF of each mutation in each well with a reference distribution of MAFs built from normal controls where all mutations were included. The Stouffer's Z-score was then calculated from the p-values of two wells, weighted by their number of UIDs.

[1032] A sample was scored as positive when any of its mutations had a value above the corresponding thresholds for any of the following three criteria: 1) the difference between its MAF and the corresponding maximum MAF observed for that mutation in the controls, 2) the ratio of its Stouffer's Z-score to the average of the highest six non-zero Stouffer's Z-scores for the same mutation in the controls, or 3) its Stouffer's Z-score alone when the mutation was not seen in the controls.

[1033] Sensitivity and specificity were obtained from a 10-fold cross validation. In each round, Pap brush samples from 90% of the 714 women without cancer served as controls. In each of the ten rounds, the remaining 10% of the Pap brush samples from women without cancer were scored to obtain specificity. All other samples were scored once in each of the 10 rounds for a total of ten times, and were considered to be positive overall if they scored

positive more than half of the time (i.e. 5 or more rounds). The mutations in the samples that scored positive are listed in Table 15.

[1034] The analysis of the plasma samples was done using an empirical Bayes approach. A Beta distribution was first fitted based on the MAFs in a set of controls using maximum likelihood estimation. The MAFs of all mutations were then adjusted accordingly. A p-value was calculated for each mutation in each well by comparison to the distribution of adjusted MAFs among the controls. An overall p-value for every mutation was obtained as the product of the p-values from all 6 wells. Sensitivity and specificity were obtained from a 10-fold cross validation. In each round, normal plasma samples from 192 healthy individuals served as controls, as for the Pap brush samples described above. A sample was considered to be positive if it was positive in 5 or more rounds. The mutations in the samples that scored positive are listed in Table 17.

[1035] Confidence intervals for sensitivities and specificities were calculated assuming binomial distributions with the actual sensitivities and specificities set as the corresponding success probabilities.

Aneuploidy detection and analysis

[1036] For each sample, a single primer pair was used to amplify ~38,000 loci of long interspersed nucleotide elements (LINEs) throughout the genome (see, e.g., Kinde et al., 2012 *PLoS One* 7:e41162). Massively parallel sequencing was performed on Illumina instruments. One of the primers include an UID to as a molecular barcode as described above to reduce error rates associated with PCR and sequencing. The sequencing data were then processed to identify significant single chromosomal arm gains or losses, as well as allelic imbalance on 39 chromosome arms, using **W**ithin-**S**ample **A**neup**L**oidy **D**etecti**O**n (WALDO) software (see, e.g., Example 6). WALDO incorporates a support vector machine (SVM) to discriminate between aneuploid and euploid samples. The SVM was trained using 3150 synthetic aneuploid samples with low neoplastic content and 677 euploid peripheral white blood cell (WBC) samples. A sample was scored as positive (aneuploid), if the SVM discriminant score exceeded a given threshold, or if significant gains of chromosome arms 7q

and 8q were observed. These chromosome arms are frequently gained in both endometrial and ovarian cancers (see, e.g., Cancer Genome Atlas Research, 2013 *Nature* 497:67-73; and Cancer Genome Atlas Research, 2011 *Nature* 474:609-615).

Results

Evaluation of somatic mutations in Pap brush samples from patients with endometrial or ovarian cancer

[1037] The amount of DNA shed from neoplastic cells was expected to be a minor fraction of the total DNA in the Pap brush samples, with most DNA emanating from normal cells. Therefore, a sensitive, PCR-based error-reduction technology, called Safe-Sequencing System (Safe-SeqS), was used to identify mutations in these samples (see Methods and Materials). In brief, primers were designed to amplify 139 regions, covering 9,392 distinct nucleotide positions within the 18 genes of interest (Table 39). Three multiplex PCR reactions, each containing non-overlapping amplicons, were then performed on each sample.

[1038] This assay was applied to Pap brush samples of 382 women with endometrial cancer, 245 women with ovarian cancer, and 714 women without cancer. It was found that 81% of the patients with endometrial cancers had detectable mutations, including 78% of patients with early-stage (stages I and II) disease and 89% of the patients with late-stage disease (stages III and IV; Table S2**)**. The most commonly mutated genes were *PTEN* (64%), *TP53* (41%), *PIK3CA* (31%), *PIK3R1* (29%), *CTNNB1* (21%), *KRAS* (18%), *FGFR2* (11%), *POLE* (9%), *APC* (9%), *FBXW7* (8%), *RNF43* (7%), and *PPP2R1A* (5%). The median mutant allele fraction (MAF) was 4.0% (95% confidence interval (CI): 3.5% to 4.5%) (Table 15).

[1039] Twenty-nine percent of 245 ovarian cancer patients harbored detectable mutations in their Pap brush samples. These included 28% of patients with early-stage disease and 30% of patients with late-stage disease (Table 14). The most commonly mutated genes were *TP53* (74%). The median MAF was 0.54% (95% CI: 0.4%% to 0.87%) (Table 15). This assay was also applied to 714 women without cancer and found that 1.3% had a detectable mutation, yielding a specificity of 98.7% (95% CI: 97.6% to 99.4%) (Fig. 20).

[1040] Tumor tissue was available from 83% and 84% of endometrial and ovarian cancer patients who donated Pap brush samples, respectively. Using the same multiplex assay applied to the Pap brush samples, a driver gene mutation was identified in 98% and 82% of the endometrial and ovarian cancer tissues, respectively (Table 16). Of the endometrial and ovarian cancer patients with a driver mutation identified in their primary tumor, 85% and 29%, respectively, had mutations in their Pap brush samples. Conversely, of the positive Pap brush samples from patients with endometrial or ovarian cancers, 93% contained at least one driver gene mutation that was identical to that observed in their primary tumor. The fraction of Pap brush samples with mutations that were also found in the primary tumors was higher in endometrial cancer patients (97%) than in ovarian cancer patients (73%).

Evaluation of aneuploidy in Pap brush samples

[1041] In addition to somatic mutations, aneuploidy is found in the great majority of endometrial and ovarian cancers (see, e.g., Cancer Genome Atlas Research, 2013 *Nature* 497:67-73; Cancer Genome Atlas Research, 2011 *Nature* 474:609-615; and Vogelstein et al., 2013 *Science* 339:1546-1558). To assess aneuploidy, a PCR-based was used method to amplify ~38,000 loci of long interspersed nucleotide elements (LINEs) with a single primer pair. LINEs have spread throughout the genome via retrotransposition and are found on all 39 non-acrocentric autosomal arms. After sequencing, the data was processed to identify gains or losses on single chromosome arms.

[1042] Aneuploidy was detected in the Pap brush samples of 38% (n = 382) of patients with endometrial cancer, including 34% and 51% of those with early- and late-stage disease, respectively (Table 14). Aneuploidy was also detected in the Pap brush samples of 11% (n = 245) of ovarian cancer patients, including 15% and 9.3% of those with early- and late-stage disease, respectively (Table 14). In endometrial and ovarian cancers, the most commonly altered arms were 4p, 7q, 8q, and 9q. In contrast, when the aneuploidy assay was applied to the Pap brush samples of 714 women without cancer, only one woman was positive (Fig. 20).

[1043] Even if a sample does not contain a genetic alteration in one of the 18 genes assessed, it might still be aneuploid and detectable by methods provided herein. This conjecture was

supported by identification of six patients (three with endometrial and three with ovarian cancers) who had no mutations in their Pap brush samples or primary tumors (when available), but whose Pap brush samples displayed aneuploidy. The combined test incorporating the above-described assays for mutations plus aneuploidy, was dubbed "PapSEEK." PapSEEK scores a sample as positive if it either harbors a mutation or an abnormal chromosome arm number. Eighty-one percent of the Pap brush samples from women with endometrial cancers were PapSEEK-positive, including 78% of patients with early-stage disease and 92% of patients with late-stage disease (Fig. 21 and Fig. 22). Thirty-three percent of the Pap brush samples from women with ovarian cancers were PapSEEK-positive, including 34% of patients with early-stage disease and 33% of patients with late-stage disease (Fig. 21 and Fig. 22). Only 1.4% of the Pap brush samples from 714 women without cancer were PapSEEK-positive, yielding a specificity of 98.6% (95% CI: 97.4% to 99.3%) (Fig. 20).

Evaluation of Tao brush samples from patients with ovarian or endometrial cancers

[1044] A more direct, minimally invasive sampling of the intrauterine cavity (rather than the endocervical canal) might increase the sensitivity of this approach for detecting gynecologic cancers. To explore this possibility, intrauterine samples were collected using a Tao brush, which is a flexible, narrow brush covered by a retractable outer sheath that allows direct sampling of the entire endometrial cavity without injury to the myometrium or contamination from the cervical canal. It has been approved by the Food and Drug Administration for endometrial sampling and can be used in an outpatient setting without the need for anesthesia. Advantageous to a potential screening test, it is well-tolerated by patients.

[1045] PapSEEK was applied to Tao brush samples collected from 123 patients with endometrial cancers, 51 patients with ovarian cancers, and 125 women without cancer. Ninety-three percent of the Tao brush samples from endometrial cancer patients contained genetic alterations detected by PapSEEK, including 90% and 98% of patients with early-, and late-stage disease, respectively (Fig. 22). The most commonly mutated genes in the Tao brush samples were *PTEN* (63%), *TP53* (42%), *PIK3CA* (36%), *PIK3R1* (20%), *KRAS*

(17%), *CTNNB1* (15%), *FGFR2* (15%), *RNF43* (11%), *PPP2R1A* (7%), *POLE* (7%), and *FBXW7* (6%), similar to that observed in the Pap brush samples. The median MAF was 24.7% (95% CI: 21.3% to 26.9%), considerably higher than observed in the Pap brush samples, in which the median MAF was 4.0% (95% CI: 3.5% to 4.5%; Table S4).

[1046] Genetic alterations detectable by PapSEEK were found in 45% (95% CI: 31% to 60%) of the Tao brush samples from 51 women with ovarian cancers, including 47% and 44% of patients with early-, and late-stage, respectively (Fig. 22). The most commonly mutated genes were *TP53* (86%), consistent with the data on Pap brush samples. The median MAF was 0.88% (95% CI: 0.61% to 2.8%), which was higher than in the Pap brush samples (median 0.54%; 95% CI: 0.4% to 0.87%; Table 15).

[1047] PapSEEK was applied to the Tao brush samples from 125 women without cancer. None (0%) of these women tested positive for mutations, yielding a specificity of 100% (95% CI: 97% to 100%; Fig. 20).

[1048] Tao brush and Pap brush samples were available from the same women in 145 patients (103 with endometrial and 42 with ovarian cancers). In endometrial cancers, PapSEEK was positive in 91% of the Tao brush samples and in 81% of the Pap brush samples ($p = 0.02$, mid-P McNemar test). Similarly, the fraction of ovarian cancer patients with a positive PapSEEK test was higher for Tao brush (45%) than for Pap brush (17%; $p = 0.002$, mid-P McNemar test; Table 13).

[1049] Tumor tissue was available from 90% and 88% of patients with endometrial and ovarian cancers who donated Tao brush samples, respectively. PapSEEK identified driver gene mutations in 97% and 80% of the endometrial and ovarian cancer tissues, respectively (Table 16). Of the endometrial and ovarian cancer patients with a driver mutation identified in their primary tumor, 93% and 42%, respectively, had mutations detectable in their Tao brush samples. Conversely, of the positive Tao brush samples from patients with endometrial or ovarian cancers, 91% contained at least one driver gene mutation that was identical to that observed in their primary tumor. The fraction of Tao brush samples with mutations that were also found in the primary tumors was higher in endometrial cancer patients (97%) than in ovarian cancer patients (53%).

Evaluation of ctDNA in patients with ovarian cancers

[1050] Ovarian cancers that were inaccessible by Pap or Tao brush sampling due to anatomical or other factors might be detectable by circulating tumor DNA (ctDNA) in plasma. This was tested in 83 ovarian cancer patients who had donated both Pap brush and plasma samples. Due to the smaller size of degraded ctDNA, primers were designed to amplify short 67 to 81 bp DNA fragments, covering 1,931 distinct nucleotide positions within 16 genes of interest. To demonstrate the specificity of this assay, it was applied it to plasma samples from 192 healthy individuals; none (0%) tested positive, yielding a specificity of 100% (95% CI: 98% to 100%).

[1051] It was found that 43% (95% CI: 33% to 55%) of the plasma from the 83 patients with ovarian cancers had detectable ctDNA. The mutations detected are listed in Table 17. As expected, the sensitivity for ctDNA in plasma was higher in patients with late-stage tumors than early-stage tumors (56% vs. 35%; Fig. 23). For early-stage disease, the median MAF in the plasma was 0.85%, which was less than the median MAF (5.7%) in the Pap smears. At least one of the mutations identified in the plasma could be identified in 88% of the corresponding primary tumor.

[1052] In the Pap brush samples from this same cohort of 83 patients, 40% were positive by the PapSEEK test. The individuals scoring positive in their Pap brush and plasma samples only partially overlapped (Fig. 21). As a result, 63% (95% CI: 51% to 73%) of patients were positive with at least one of the two tests. Those who tested positive included 54% of patients with early-stage disease and 75% with late-stage disease, respectively (Table 13, Fig. 23).

Discussion

[1053] As described herein, a multiplex PCR-based test (PapSEEK) was designed and applied to detect genetic alterations in Pap brush or Tao brush samples. These samples are minimally invasively and conveniently obtained during routine office visits. The majority of endometrial cancers could be detected with PapSEEK: 93% with Tao Brush and 81% with

Pap brush. A substantial fraction of ovarian cancers could also be detected with PapSEEK: 45% with Tao Brush and 33% with Pap brush. The specificity of PapSEEK was high, with only 0% and 1.4% of women without cancer testing positive with Tao and Pap brush samples, respectively (Fig. 24). It was also demonstrated that assays for ctDNA in plasma could be used in conjunction with PapSEEK on Pap brush samples, increasing the sensitivity of detecting ovarian cancer to 63%.

[1054] It was notable that the sensitivity for detecting early-stage ovarian cancers was as high as that for late-stage disease (47% vs. 44% for Tao; 34 % vs. 33% for Pap). Without wishing to be bound by theory, there are at least two possible explanations for this unexpected but enticing finding. First, it has been shown that some ovarian cancers originate in the fallopian tubes, which could facilitate their early detection with PapSEEK when tumor cells are shed into the uterine cavity. Second, in late-stage tumors, the fallopian tubes are often matted and obliterated by the disease and thus less likely to serve as a conduit for tumor cells to pass into the uterus or endocervical canal. In this setting, the addition of ctDNA analysis in plasma to Pap or Tao brush sampling may be particularly beneficial.

[1055] A subset of samples tested herein was composed of high-grade, early-stage cancers. Currently available diagnostic modalities have low sensitivities for these lesions (see, e.g., Fishman et al., 2005 *Am J Obstet Gynecol* 192:1214-1221; Sharma et al., 2012 *Ultrasound Obstet Gynecol* 40:338-344; and Hamilton et al., 2006 *British journal of cancer* 94:642-646). Though the high-grade subtypes comprise only about 10% of incident endometrial cancers, they account for more than 40% of deaths from the disease (see, e.g., Moore et al., 2011 *Clin Obstet Gynecol* 54:278-291). As these high-grade cancers often arise from a background of atrophic endometrium and can metastasize prior to visible abnormalities on imaging, transvaginal ultrasound has a limited role in screening and early diagnosis. Thus it was encouraging that PapSEEK detected 85% (n=34) and 89% (n=9) of high-grade endometrial cancers confined to the endometrium in the Pap and Tao brush samples, respectively. In the case of ovarian cancers, the tested cohort included only a small number of early-stage, high-grade cases, consistent with the unfortunate fact that these cancers are often diagnosed only at advanced stages. Nevertheless, the finding that 36% (n=11) were positive with combined

Pap and plasma sample testing, and that 80% (n=5) were positive in Tao brush samples, is notable.

[1056] The study described herein was retrospective. The samples that were examined were derived from patients with known cancers, even though a substantial fraction was from patients with early-stage lesions. In a screening setting, the cancers would advantageously be at an earlier stage, and the sensitivities for detection would be expected to be closer to the sensitivity for early-stage cancers observed in the present study. Moreover, the age ranges of the controls and cases are typically better matched in a prospective study than in the present retrospective study. Some of the ovarian cancer patients who had mutations detectable in their Pap brush or Tao brush samples did not have the identical mutations in their primary tumors. This was not an issue with endometrial cancers, wherein at least one mutation in the brush samples was nearly always (97%) found in the corresponding primary tumors. But this phenomenon was observed in ovarian cancer patients, particularly with the Tao brush. At least one mutation identifiable in the Pap brush could be identified in 73% of the corresponding primary ovarian tumors, while the same was true for only 53% of the Tao brush samples.

[1057] Without wishing to be bound by theory, one possible explanation for the discordance between the mutations in brush samples and ovarian cancers from the same patients is that the assay detects mutations that do not exist *in vivo*, representing technical artifacts. It is not believed that this is likely, however, given that the specificity of the assays was 100% and 99% in Tao brush and Pap brush samples, respectively, from women without cancer. Another possible explanation is tumor heterogeneity. Only a small part of the tumors that were analyzed was sampled and sequenced, and the additional mutations found in the Pap smear or intrauterine samples could represent mutations from other parts of the tumor. It is also possible that some mutations were from small synchronous endometrial cancers or early, premalignant endometrial lesions that were unnoted by the pathologist. A significant proportion of women with ovarian cancer have synchronous endometrial cancer, with risk factors including Lynch syndrome, polycystic ovarian syndrome, perimenopause, obesity, nulliparity, and unopposed estrogen replacement therapy (see, e.g., Al Hilli et al., 2012 *Gynecologic oncology* 125:109-113; Walsh et al., 2005 *Obstetrics and gynecology* 106:693-

699; Zaino et al., 2001 *Gynecologic oncology* 83:355-362; and Song et al., 2014 *Int J Gynecol Cancer* 24:520-527).

[1058] Though tumor heterogeneity, or multiple synchronous tumors are feasible explanations that are often used to explain discordances in liquid biopsy studies, without wishing to be bound by theory, it is possible that clonal expansions of non-malignant cells may play a role in the present observations. Clonal proliferations that are not considered neoplastic have been described in the uterine lavage, bone marrow, skin, and other tissues (see, e.g., Steensma et al., 2015 *Blood* 126:9-16; Coombs et al., 2017 *Cell Stem Cell* 21(3):374-382; Young et al., 2016 *Nat Commun* 7:12484; Krimmel et al., 2016 *Proc Natl Acad Sci U S A* 113:6005-6010; and Nair et al., 2016 *PLoS Med* 13:e1002206). Of particular interest are the clonal proliferations of endometrial cells that cause endometriosis, a sometimes debilitating condition that affects millions of women. It has recently been shown that these lesions, which can occur throughout the abdomen and are derived from endometrium, are clonal proliferations that can be driven by the same mutations detected in endometrial cancers (see, e.g., Anglesio et al., 2017 *N Engl J Med* 376:1835-1848). Without wishing to be bound by theory, it is possible that the hormonal and physiologic changes contributing to or resulting from ovarian cancers stimulate or select for such clonal proliferations in the endometrial lining. On one hand, this possibility argues against the exquisite specificity that is the conceptual basis for all liquid biopsies. On the other hand, it could actually enhance the sensitivity of detection of ovarian cancers, without diminishing specificity, if large clonal proliferations are almost exclusively found in women with gynecologic malignancies. Clonal proliferations that account for >0.03% of the total cells in the endometrial lining are detectable by methods provided herein.

Example 5: Detecting urologic malignancies using a combination approach cancer screening tests

[1059] According to the American Cancer Society, 79,030 new cases of bladder cancer (BC) and 18,540 deaths are estimated to occur in the United States alone in 2017 (see, e.g., Siegel et al., 2017 *CA Cancer J Clin* 67:7-30), with many BC patients suffer with multiple relapses

prior to progression, providing ample lead-time for early detection and treatment prior to metastasis (see, e.g., Netto, 2013 *Adv Anat Pathol* 20:175-203). Urine cytology and cystoscopy with transurethral biopsy (TURB) are currently the gold standard for diagnosis and follow-up in bladder cancer. While urine cytology has value for the detection of high-grade neoplasms, it is unable to detect the vast majority of low-grade tumors (see, e.g., Netto et al., 2016 *Urol Clin North Am* 43:63-76; Lotan et al., 2003 *Urology* 61:109-18; and Zhang et al., 2016 *Cancer Cytopathol* 124:552-564). This fact, together with the high cost and invasive nature of repeated cystoscopy and TURB procedures, have led to many attempts to develop novel noninvasive strategies including urine or serum based genetic and protein assays for screening and surveillance (see, e.g., Kawauchi et al., 2009 *Hum Pathol* 40:1783-1789; Kruger et al., 2003 *Int J Oncol* 23:41-48; Skacel et al., 2003 *J Urol* 169:2101-2105; Sarosdy et al., 2006 *J Urol* 176:44-47; Moonen et al., 2007 *Eur Urol* 51:1275-80; Fradet et al., 1997 *Can J Urol* 4:400-405; Yafi et al., 2015 *Urol Oncol* 33:66.e25-66.e31; Serizawa et al., 2010 *Int J Cancer* 129(1):78-87; Kinde et al., 2013 *Cancer Res* 73:7162-7167; Hurst et al., 2014 *Eur Urol* 65:367-369; Wang et al., 2014 *Oncotarget* 5:12428-12439; Ralla et al., 2014 *Crit Rev Clin Lab Sci* 51:200-231; Ellinger et al., 2015 *Expert Rev Mol Diagn* 15:505-516; Bansal et al., 2014 *Clin Chim Acta* 436:97-103; Goodison et al., 2012 *PLoS One* 7:e47469; and Allory et al., 2014 *Eur Urol* 65:360-366). Currently available U.S. Food and Drug Administration (FDA) approved assays include ImmunoCyt test (Scimedx Corp), nuclear matrix protein 22 (NMP22) immunoassay test (Matritech), and multitarget FISH (UroVysion) (see, e.g., Kawauchi et al., 2009 *Hum Pathol* 40:1783-1789; Kruger et al., 2003 *Int J Oncol* 23:41-48; Skacel et al., 2003 *J Urol* 169:2101-2105; Sarosdy et al., 2006 *J Urol* 176:44-47; Moonen et al., 2007 *Eur Urol* 51:1275-80; Fradet et al., 1997 *Can J Urol* 4:400-405; and Yafi et al., 2015 *Urol Oncol* 33:66.e25-66.e31). Sensitivities between 62% and 69% and specificities between 79% and 89% have been reported for some of these tests; however, due to assay performance inconsistencies, cost or required technical expertise, integration of such assays into routine clinical practice has not yet occurred. Further, because urine cytology is relatively insensitive for the detection of recurrence, cystoscopies are performed as often as every three months in such patients in the U.S, and the cost of managing these

patients is in aggregate higher than the cost of managing any other type of cancer, and amounts to 3 billion dollars annually (see, e.g., Netto et al., 2010 *Pathology* 42:384-394).

[1060] Further, the annual incidence of these upper tract urothelial carcinomas (UTUCs) in Western countries is 1-2 cases per 100,000, but occurs at a much higher rate in populations exposed to aristolochic acid (AA) (Chen et al., 2012 *Proc Natl Acad Sci U S A*, 109(21):8241-8246; and Grollman et al., 2013 *Environ Mol Mutagen*, 54(1):1-7; and Lai et al., 2010 *J Natl Cancer Inst*, 102(3):179-186). Nephroureterectomy can be curative for patients with UTUC when it is detected at an early stage (Li et al., 2008 *Eur Urol.* 54(5):1127-34). However, these cancers are largely silent until the onset of overt clinical symptoms, typically hematuria, and as a result, most patients are diagnosed only at an advanced stage (Roupret et al., 2015 *Eur Urol.* 68(5):868-79). Diagnostic tests for the detection of early-stage UTUC are not currently available.

[1061] A broadly applicable approach for non-invasive detection of cancer (e.g., an early-stage cancer such as BCs or UTUCs) could be both medically and economically important.

[1062] This Example describes a new blood test, called UroSEEK, which addresses the problematic issues described above. In this test, DNA from urine samples can be used in an assay (e.g., a PCR-based, multiplex test) to simultaneously assess genetic alterations that commonly occur in BCs or UTUCs. A schematic of the approach used in the bladder cancer study is provided in Fig. 25, and a schematic of the approach used in the UTUC study is provided in Fig. 31.

Materials and Methods

Patients and Samples

[1063] Urine samples were collected prospectively from patients in four participating institutions including Johns Hopkins Hospital, Baltimore, MD, USA; A.C. Camargo Cancer Center, Sao Paulo, Brazil; Osaka University Hospital, Osaka, Japan; and Hacettepe University Hospital, Ankara, Turkey. The study was approved by the institutional Review Boards of Johns Hopkins Hospital and all other participating institutions. Proper material

transfer agreements were obtained. Patients with a known history of malignancy other than bladder cancer were excluded from the study. The study included two cohorts of patients.

[1064] The Early Detection cohort comprised 570 patients who were referred to a urology clinic in one of the above hospitals because of hematuria or lower urinary tract symptoms (Table 18). The second cohort (322 patients) represented patients with prior established diagnosis of Bladder Cancer (BC) who are on surveillance for disease recurrence (Surveillance Cohort). These patients' primary tumors harbored mutations in at least one of the 11 genes assessed through the multiplex or singleplex assays. A minimum follow-up of 12 months was from date of urine collection was required for cases with no evidence of incident or recurrent tumors in the Early Detection or Surveillance cohorts, respectively. Urine samples were collected prior to any procedures, such as cystoscopy, performed during the patients' visits. A total of 892 urine samples were analyzed in the study, composed of two type of samples. The first was residual urinary cells after processing with standard BD SurePath™ liquid-based cytology protocols (Becton Dickinson and Company; Franklin Lakes, NJ, USA). To allow for standard-of-care, residual SurePath® fluids were kept refrigerated for 6-8 weeks prior to submission for DNA purification to allow for any potential need for repeat cytology processing of the same sample. The second sample type was composed of bio-banked fresh urine samples in which 15 - 25 mL of voided urine samples were stored at 4°C for up to 60 min prior to centrifugation (10 min at 500 g) and the pellets stored at minus 80°C prior to DNA purification. Urines from 188 healthy individuals of average age 26 were also obtained and processed identically to the bio-banked fresh urine samples.

[1065] Formalin-fixed paraffin-embedded (FFPE) tumor tissue samples from trans-urethral resections (TURB) or cystectomies were collected in 413 of the 892 cases. When several different tumors from the same patient were available (because of recurrences), the earliest tumor tissue obtained following the donation of the urine sample was used in the Early Detection Cohort. In the surveillance cohort, the tumors preceding the donation of the urine sample was used in 146 of the 322 patients. In the other 176 Surveillance cases, the earliest tissue obtained following the donation of the urine sample was used. A genitourinary pathologist reviewed all histologic slides to confirm the diagnosis and select a representative

tumor area with as high tumor cellularity as possible for that case. Corresponding FFPE blocks were cored with a sterile 16-gauge needle. One to three cores were obtained per tumor and placed in 1.5mL sterile tubes for DNA purification, as described elsewhere (see, e.g., Kinde et al., 2013 *Cancer Res* 73:7162-7167). Electronic medical records were reviewed to obtain medical history and follow up data in all patients.

UTUC Cohort Studied

[1066] Sequential patients with UTUC scheduled to undergo a radical unilateral nephroureterectomy at National Taiwan University Hospital in 2012-2016 were asked to participate in the study. All patients provided informed consent using the consent form and study design reviewed and approved by the Institutional Review Boards at National Taiwan University and Stony Brook University. A total of 56 UTUC patients were enrolled in the study after excluding four patients with gross hematuria and one patient with a tumor-urine DNA mismatch by identity testing. Urinary cell DNA from 188 urine samples donated by healthy individuals in the U.S. of average age 40, range 19 to 60 years old, was used to assess the specificity of the UroSEEK test. White blood cell (WBC) DNA from 94 normal individuals from the U.S. was used to evaluate the technical specificity of the PCR analysis.

Biological samples – UTUC Cohort

[1067] Urine samples were obtained from patients one day prior to surgery. Urinary cells were isolated by centrifugation at 581g for 10 minutes at room temperature, washed thrice in saline using the same centrifugation conditions, and stored frozen until DNA was isolated using a Qiagen kit #937255 (Germantown, MD). DNA was purified from fresh-frozen resected samples of upper tract tumors and renal cortex by standard phenol-chloroform extraction procedures as described elsewhere (see, e.g., Chen et al., 2012 *Proc Natl Acad Sci USA*, 109(21):8241-8246; and Jelakovic et al., 2012 *Kidney Int.* 81(6):559-67). One upper urinary tract tumor per patient was analyzed; for cases with tumors at multiple sites, renal pelvic tumors were preferentially selected whenever available. Formalin-fixed, paraffin-

embedded tumor samples were staged and graded by a urologic pathologist, and the presence of one or more upper tract urothelial carcinomas was confirmed by histopathology for each enrolled subject. Pertinent clinical and demographic data were obtained by a chart review of each subject. eGFR was calculated by the MDRD equation (see, e.g., Levey et al., 2006 *Ann Intern Med.* 145(4):247-54) and used to determine CKD stage (see, e.g., Levey et al., 2005 *Kidney Int.* 67(6):2089-100).

DNA adduct analysis

[1068] AL-DNA adduct (7-(deoxyadenosin-N6-yl) aristolactam I; dA-AL-I) levels in 2 μg of DNA from the normal renal cortex of UTUC patients were quantified by ultra-performance liquid chromatography–electrospray ionization/multistage mass spectrometry (UPLC-ESI/MSn) with a linear quadrupole ion trap mass spectrometer (LTQ Velos Pro, Thermo Fisher Scientific, San Jose, CA) as described elsewhere (see, e.g., Yun et al., 2012 *Chem Res Toxicol.* 2012 25(5):1119-31).

Mutation analysis

[1069] Three separate assays were used to search for abnormalities in urinary cell DNA. First, a multiplex PCR was used to detect mutations in regions of ten genes commonly mutated in urologic malignancies CDKN2A, ERBB2, FGFR3, HRAS, KRAS, MET, MLL, PIK3CA, TP53, and VHL (see, e.g., Netto, 2011 *Nat Rev Urol* 9:41-51; Mo et al., 2007 *J Clin Invest* 117:314-325; Sarkis et al., 1993 *J Natl Cancer Inst* 85:53-59; Lin et al., 2010 *Urol Oncol* 28:597-602; Sarkis et al., 1994 *J Urol* 152:388-392; Sarkis et al., 1995 *J Clin Oncol* 13:1384-1390; Wu, 2005 *Nat Rev Cancer* 5:713-725; and Cancer Genome Atlas Research Network, 2014 *Nature* 507:315-322). The primer pairs used for this multiplex PCR were divided in a total of three multiplex reactions, each containing non-overlapping amplicons (see below). These primers were used to amplify DNA in 25 μL reactions as described elsewhere (see, e.g., Kinde et al., 2011 *Proc Natl Acad Sci U S A* 108:9530-9535) except that 15 cycles were used for the initial amplification. Second, the *TERT* promoter

region was evaluated. A single amplification primer was used to amplify a 73-bp segment containing the region of the *TERT* promoter known to harbor mutations in BC (see, e.g., Kinde et al., 2013 *Cancer Res* 73:7162-7167). The conditions used to amplify it were the same as used in the multiplex reactions described above except that Phusion GC Buffer (Thermo-Fisher) instead of HF buffer was used and 20 cycles were used for the initial amplification. The *TERT* promoter region could not be included in the multiplex PCR because of the high GC content of the former. PCR products were purified with AMPure XP beads (Beckman Coulter, PA, USA) and 0.25% of the purified PCR products (multiplex) or 0.0125% of the PCR products (*TERT* singleplex) were then amplified in a second round of PCR, as described elsewhere (see, e.g., Wang et al., 2016 *Elife* 5:10.7554/eLife.15175). The PCR products from the second round of amplification were then purified with AMPure and sequenced on an Illumina instrument. For each mutation identified, the mutant allele frequency (MAF) was determined by dividing the number of uniquely identified reads with mutations (see, e.g., Kinde et al., 2011 *Proc Natl Acad Sci U S A* 108:9530-9535) by the number of total uniquely identified reads. Each DNA sample was assessed in two independent PCRs, for both the *TERT* promoter and multiplex assays, and samples were scored as positive only if both PCRs showed the same mutation. The mutant allele frequencies and number of UIDs listed in Table 19, Table 20, Table 22, and Table 23 refer to the average of the two independent assays.

[1070] To evaluate the statistical significance of putative mutations, DNA from white blood cells of 188 unrelated normal individuals were assessed. A variant observed in the samples from cancer patient was only scored as a mutation if it was observed at a much higher MAF than observed in normal WBCs. Specifically, the classification of a sample's ctDNA status was based on two complementary criteria applied to each mutation: 1) the difference between the average MAF in the sample of interest and the corresponding maximum MAF observed for that same mutation in a set of controls, and 2) the Stouffer's Z-score obtained by comparing the MAF in the sample of interest to a distribution of normal controls. To calculate the Z-score, the MAF in the sample of interest was first normalized based on the mutation-specific distributions of MAFs observed among all controls. Following this mutation-specific normalization, a P-value was obtained by comparing the MAF of each

mutation in each well with a reference distribution of MAFs built from normal controls where all mutations were included. The Stouffer's Z-score was then calculated from the p-values of two wells, weighted by their number of UIDs. The sample was classified as positive if either the difference or the Stouffer's Z-score of its mutations was above the thresholds determined from the normal WBCs. The threshold for the difference parameter was defined by the highest MAF observed in any normal WBCs. The threshold for the Stouffer's Z-score was chosen to allow one false positive among the 188 normal urine samples studied.

Analysis of aneuploidy.

[1071] Aneuploidy was assessed with Fast-SeqS, which uses a single primer pair to amplify ~38,000 loci scattered throughout the genome (see, e.g., Kinde et al., 2012 *PLoS One* 7:e41162). After massively parallel sequencing, gains or losses of each of the 39 chromosome arms covered by the assay were determined using a bespoke statistical learning method. A Support vector machine (SVM) was used to discriminate between aneuploid and euploid samples. The SVM was trained using 3150 low neoplastic cell fraction synthetic aneuploid samples and 677 euploid peripheral white blood cell (WBC) samples. Samples were scored as positive when the genome-wide aneuploidy score was >0.7 and there was at least one gain or loss of a chromosome arm.

Identity checks.

[1072] A multiplex reaction containing 26 primers detecting 31 common SNPs on chromosomes 10 and 20 was performed using the amplification conditions described above for the multiplex PCR. The primers used for this identity evaluation are listed in Fig. 34 (Table 42) for bladder cancer cohorts and Fig. 33 (Table 41) for UTUC cohorts.

Statistical Analysis

[1073] Performance characteristics of urine cytology, UroSEEK and its three components was calculated using MedCalc statistical software (medcalc.org/calc/diagnostic_test.php).

Results

Early Detection Cohort characteristics.

[1074] A flow diagram indicating the number of patients evaluated in this study and the major results is provided in Fig. 26.

[1075] A total 570 patients were included in the Early Detection cohort, each with one urine sample analyzed. 90% of the patients had hematuria, 3% had lower urinary tract symptoms (LUTS), and 9% had other indications suggesting they were at risk for BC. The median age of the participants was 58 years (range 5 to 89) (Table 18). 70% of the patients were male. 175 (31%) of patients developed BC after a median follow-up period of 18 months (range 0 to 40 months). For each patient who developed BC, two other patients were selected who presented with similar symptoms but did not develop BC during the follow-up period. By design, then, the fraction of cases in this cohort developing BC was higher than the fraction (5%) of patients with similar presentations that would have developed BC in standard clinical practice. The characteristics of the tumors developing in the 570 patients are summarized below.

Demographic, clinical and genetic features of the early detection cohort.

Gender	n	%	Ten-gene multiplex positive	TERT positive	Aneuploidy positive	UroSEEK positive	Cytology Positive*	UroSEEK or Cytology positive*
Males without recurrence	172	59%	3 (2%)	10 (6%)	2 (1%)	13 (8%)	0 (0%)	13 (8%)
Males with recurrence	32	11%	26 (81%)	21 (66%)	19 (59%)	29 (91%)	16 (50%)	30 (94%)
Females without recurrence	81	28%	2 (2%)	2 (2%)	1 (1%)	5 (6%)	0 (0%)	5 (6%)
Females with recurrence	9	3%	4 (44%)	4 (44%)	3 (33%)	6 (67%)	1 (11%)	6 (67%)
Indication								
Hematuria without recurrence	346	61%	6 (2%)	15 (4%)	5 (1%)	22 (6%)	0 (0%)	17 (5%)
Hematuria with recurrence	163	29%	108 (66%)	90 (55%)	76 (47%)	134 (82%)	18 (11%)	32 (2%)
LUTS without recurrence	11	2%	0 (0%)	2 (18%)	0 (0%)	2 (18%)	0 (0%)	2 (18%)

Genetic analysis in bladder cancer cohorts.

[1076] Three separate tests were performed for genetic abnormalities that might be found in urinary cells derived from BC (Fig. 26). First, mutations were evaluated in selected regions of ten genes that have been shown to be frequently altered in urothelial tumors (Table 19). For this purpose, a specific set of primers were designed that allowed detection of mutations in as few as 0.03% of urinary cells. The capacity to detect such low mutant fractions was a result of the incorporation of molecular barcodes in each of the primers, thereby substantially reducing the artifacts associated with massively parallel sequencing. Second, *TERT* promoter mutations were evaluated. A singleplex PCR was used for this analysis because the unusually high GC-content of the *TERT* promoter precluded its inclusion in the multiplex PCR design. Third, the extent of aneuploidy was evaluated using a technique in which a single PCR is used to co-amplify ~38,000 members of a subfamily of long interspersed nucleotide element-1 (L1 retrotransposons, also called LINEs). L1 retrotransposons, like other human repeats, have spread throughout the genome via retrotransposition and are found on all 39 non-acrocentric autosomal arms.

[1077] The multiplex assay detected mutations in 68% of the 175 urinary cell samples from the individuals that developed BC during the course of this study (95% CI 61% to 75%) (Table 19). A total of 246 mutations were detected in 8 of the ten target genes (Fig. 27A and Table 19). The mean mutant allele frequency in the urinary cells with detectable mutations was 18% and ranged from 0.17% to 99%. The most commonly altered genes were TP53 (45% of the total mutations) and FGFR3 (20% of the total mutations; Fig. 27A). At the thresholds used, 1.7% of the 395 patients in the Early Detection Cohort who did not develop BC during the course of the study had a detectable mutation in any of the ten genes. At the same thresholds, none of the 188 urinary cell samples from healthy individuals had any mutation in any of the ten genes assayed (100% specificity, 95% CI 98% to 100%).

[1078] Mutations in the *TERT* promoter were detected in 57% of the 175 urinary cell samples from the patients that developed cancer during the study interval (95% CI 49% to

64%; Table 20). The mean *TERT* mutant allele frequency in the urinary cells was 14% and ranged from 0.18% to 78%. Mutations were detected in 3 positions: 98% of the mutations were at hg1295228 (79%) and hg 1295250 (19%), which are 66 and 88 bp upstream of the transcription start site, respectively. These positions have been previously shown to be involved in the appropriate transcriptional regulation of *TERT*. In particular, the mutant alleles recruit the GABPA/B1 transcription factor, resulting in the H3K4me2/3 mark of active chromatin and reversing the epigenetic silencing present in normal cells. 4% of the 395 patients in this cohort who did not develop BC during the course of the study had a detectable mutation in the *TERT* promoter. Only one of the 188 urinary samples from healthy individuals harbored a *TERT* promoter mutation.

[1079] Aneuploidy was detected in 46% (95% CI 39% to 54%) of the 175 urinary cell samples from the patients that developed BC during the course of the study (Table 20 and Table 21). The most commonly altered arms were 5q, 8q, and 9p. All three of these arms harbor well-known oncogenes and tumor suppressor genes which have been shown to undergo copy number alterations in many cancers, including BC. 1.5% of the urinary cell samples from the 395 patients who did not develop BC during the course of the study exhibited aneuploidy. None of the 188 urinary samples from healthy individuals exhibited aneuploidy when assessed with the same technology.

Comparison with primary tumors

[1080] Tumor samples from 102 of the patients enrolled in this cohort were available for comparison and were studied with the same three assays used to study the urinary cell samples (Table 20). In 91 (89%) of these 102 cancers, at least one mutation in the eleven genes studied were mutated (in the 10-gene panel or in the *TERT* promoter). Moreover, at least one of the mutations identified in the urine samples from these 102 patients was also identified in 83% of the corresponding BC (Table 19, and Table 20). Analysis of the BCs also shed light on the basis for "false negatives", i.e., the reason that 21% of urine samples from patients who developed BC had no detectable mutations in the 11 genes tested. The reason could either have been that the corresponding BC did not harbor a mutation in these

11 genes or that it did, but the fraction of neoplastic cells in the urine sample was not high enough to allow its detection with the assays used. At least one mutation in at least one of the 11 genes in 62% of the primary tumors was identified from patients with false negative urine tests for mutations (Table 22, and Table 23). The results indicate that 38% of the 29 false negative tests for mutations were due to the fact that none of the queried mutations were present in the tumor and that the other 62% of the false negatives were due to insufficient amounts of cancer cells in the urine.

UroSEEK: biomarkers in combination.

[1081] As noted above, the ten-gene multiplex assay, the *TERT* singleplex assay, and the aneuploidy assays yielded 68%, 57%, and 46% sensitivities, respectively, when used separately (Table 19, Table 20, and Table 21). 45 samples without *TERT* promoter mutations could be detected by mutations in one of the other ten genes (Fig. 28A and Table 19). Conversely, 35 samples without detectable mutations in the multiplex assay could be detected by virtue of *TERT* promoter mutations (Fig. 28A and Table 20). Ten of the urinary cell samples without any detectable mutations in the 11 genes could be detected by the assay for aneuploidy (Fig. 28A and Table 21). Thus, when the three assays were used together (test termed "UroSEEK"), and a positive result in either assay was sufficient to score a sample as positive, the sensitivity rose to 83% (95% CI 76% to 88 %). Only one of the 188 samples from healthy individuals was scored positive by UroSEEK (specificity 99.5%, CI 97% to 100%). Twenty-six (6.5%) of the 395 patients in this cohort who did not develop BC during the course of the study scored positive by the UroSEEK test (specificity 93%, CI 91% to 96%). On average, UroSEEK positivity preceded the diagnosis of BC by 2.3 months, and in eight cases by more than a year (Fig. 29A and Table 18).

UroSEEK plus cytology

[1082] As both cytology and UroSEEK tests are non-invasive and can be performed on the same urine sample, their performance in combination was assessed. There were 347 patients

in the Early Detection cohort in whom cytology was available (Table 18). Among the 40 patients who developed biopsy-proven cancer in this cohort, 17 were positive by cytology (43% sensitivity). None of the 299 patients that did not develop cancer were positive by cytology (100% specificity). UroSEEK was positive in 100% of the 17 cancer patients whose urines were positive by cytology and in 95% of the 23 cancer patients whose urines were negative by cytology. Thus, in combination, UroSEEK plus cytology afforded 95% (95% CI 83% to 99%) sensitivity, a 12% increase over UroSEEK and a 52% increase over cytology. Among the 299 patients in the early detection cohort who did not develop BC during the course of the study, 20 (6.6%) were positive by UroSEEK or cytology, giving the combination of UroSEEK and cytology a specificity of 93% (95% CI 90% to 96%).

Surveillance Cohort characteristics

[1083] The strategy for surveillance was different than the one used for early detection. Patients in whom a BC was surgically excised for treatment and diagnosis generally have tumor tissue available, and in most such tumors, a mutation can be identified. For example, it was found during the course of this study that a mutation in at least one of the 11 queried genes was present in 95.2% of BCs evaluated. All patients selected for the surveillance study had biopsy confirmed BC and had a urine sample collected 0 - 5 years after surgery. A total of 322 patients that donated urines and whose BC contained a mutation in at least one of the 11 genes analyzed were evaluated. It was determined whether a single urine sample taken a relatively short time following surgical excision of the BC could reveal residual disease in these 322 patients, as evidenced by later recurrence. 187 (58%) of the 322 patients developed clinically evident BC after a median follow-up period of 10.7 months (range 0 to 51 months). The histopathologic types and tumor stages of these patients are summarized below and detailed Table 24. The median age of the participants was 62 (range 20 to 93). As expected from the demographics of BC, 75% of the patients were male.

Demographic, clinical and genetic features of the Surveillance cohort.

Gender	n	%	Ten-gene multiplex positive	TERT positive	Aneuploidy positive	UroSEEK positive	Cytology Positive*	UroSEEK or Cytology positive*
Males without recurrence	59	30%	3 (5%)	8 (14%)	3 (5%)	10 (17%)	0 (0%)	8 (14%)
Males with recurrence	90	45%	45 (50%)	53 (59%)	20 (22%)	59 (66%)	20 (22%)	53 (59%)

Genetic analysis of Surveillance Cohort

[1084] The multiplex assay in urinary cells detected mutations in 49% of the urinary cell samples from patients that developed recurrent BC during the study interval (95% CI 45% to 60%; Table 24 and Table 25). The mean mutant allele frequency in the urinary cells with detectable mutations was 16% and ranged from 0.08% to 93%. The most commonly altered genes were FGFR3 (43% of the 134 mutations) and TP53 (30% of the 134 mutations; Fig. 27B). Seven percent of the 135 patients who did not develop recurrent BC during the course of the study had a detectable mutation in their urinary cell sample (these are considered to be false positives; see Discussion). The mean interval between a positive multiplex assay test and the diagnosis of recurrent BC was 7 months (range 0 to 51 months).

[1085] Mutations in the *TERT* promoter were detected in 51% of the urinary cell samples from patients that developed recurrent BC during the study interval (95% CI 44% to 58%; Table 26). The mean *TERT* mutant allele frequency in the urinary cells with detectable mutations was 6% and ranged from 0.23% to 43%. Mutations were detected in the same three positions observed in the urinary cells of the Early Detection cohort. 10% (95% CI 83% to 94%) of the 135 patients who did not develop recurrent BC during the course of the study had a detectable *TERT* promoter mutation in their urine sample (false positives). The mean interval between a positive *TERT* test and the diagnosis of recurrent BC was 7 months (range 0 to 40 months).

[1086] Aneuploidy was detected in 30% (95% CI 24% to 37%) of the urinary cell samples from the patients that developed recurrent BC during the course of the study (Table 27). The most commonly altered arms were 8p, 8q, and 9p, as in the Early Detection cohort. Two percent of the 135 patients who did not develop recurrent BC during the course of the study exhibited aneuploidy in at least one of their urinary cell samples.

Markers in combination – Surveillance Cohort

[1087] As noted above, the ten-gene multiplex assay, the *TERT* singleplex assay, and the aneuploidy assays yielded 49%, 51%, and 30% sensitivities, respectively, when used separately (Table 25, Table 26, and Table 27). Thirty-two samples without *TERT* promoter mutations could be detected by mutations in one of the other ten genes (Fig. 28B and Table 25). Conversely, 41 samples without detectable mutations in the multiplex assay could be detected by virtue of *TERT* promoter mutations. Three of the urinary cell samples without any detectable mutations could be detected by the assay for aneuploidy. Thus, the sensitivity of UroSEEK was 66% (95% CI 59% to 73%). Fourteen percent of the 135 patients in this cohort who did not develop BC during the course of the study scored positive by the UroSEEK test, yielding a specificity of 86% (95% CI 77% to 91%). On average, UroSEEK positivity preceded the diagnosis of BC by 7 months, and in 47 cases by more than one year (Fig. 29B and Table 24).

[1088] There were 196 patients in the Surveillance cohort for whom cytology was available (Table 24). Among the 120 patients who developed recurrent BC in this cohort, 30 (25%) were positive by cytology. Conversely, no positive cytology results were observed in patients whose tumors did not recur. UroSEEK was positive in 90% of the recurrent BC patients whose urines were positive by cytology and in 61% of the 90 recurrent BC patients whose urines were negative by cytology. Thus in combination, UroSEEK plus cytology afforded 71% sensitivity (95% CI 61.84% to 78.77) (Fig. 28D and Table 22). Among the 76 patients who did not develop recurrent BC during the course of the study and in whom cytology was available, 18% scored as positive by either cytology or UroSEEK, affording a specificity of 82% (95% CI 71% to 90%;).

Low vs. high grade urothelial neoplasms in both Early Detection and Surveillance Cohorts

[1089] The advantage of UroSEEK over cytology was particularly evident in low-grade tumors (Papillary urothelial neoplasms of low malignant potential and non-invasive low

grade papillary urothelial carcinomas). There were a total of 49 low-grade tumors evaluated in this study in whom cytology was available (six from the Early Detection cohort and 43 from the Surveillance cohort). None of these low-grade tumors were detected by cytology (0% sensitivity; 95% CI 0.0% to 6.7%). In contrast, UroSEEK detected 67% (95% CI 51% to 81%) of the low-grade tumors (identical rate of 67% in both cohorts; Fig. 30). Analogously, there were a total of 102 high-grade tumors (in-situ urothelial carcinoma, non-invasive high grade papillary urothelial carcinoma or infiltrating high grade urothelial carcinoma) evaluated in this study in whom cytology was available (34 from the Early Detection cohort and 68 in the Surveillance cohort). Cytology was positive in 45% of these patients (50% and 41% in the Early Detection and Surveillance cohorts, respectively) while UroSEEK was positive in 80% of them (100% and 71% in the Early Detection and Surveillance cohorts, respectively; see below.

Summary of the performance of Cytology vs. UroSEEK.

Biopsy Outcome Diagnosis	n	Cytology				UroSEEK			
		Positive test	Negative test	Sensitivity	95% CI	Positive test	Negative test	Sensitivity	95% CI
PUNLMP/LGTCC	49	0	49	0%	0.00% to 6.06%	33	16	67%	54.36% to 79.38%
CIS/HGTCC/INTCC	102	46	56	45%	33.63% to 52.21%	82	20	80%	71.03% to 86.39%
Total	151								

UTUC Cohort characteristics

[1090] Thirty-two females and twenty-four males ranging in age from 39-85 years participated in the study (see below; individual data are in Table 28). This gender distribution, atypical of UTUC patients in Western countries where males predominate (Shariat et al., 2011 *World J Urol.* 29(4):481-6), is consistent with previous epidemiologic studies of Taiwanese individuals with known exposures to AA (see, e.g., Chen et al., 2012 *Proc Natl Acad Sci U S A*, 109(21):8241-8246). Tobacco use was reported by 18% of this cohort, all males. Based on estimated glomerular filtration rate (eGFR) values, renal function was unimpaired (chronic kidney disease (CKD) stage 0-2) in 45% of the subjects, while mild-to-moderate renal disease (CKD stage 3) or severe disease (CKD stages 4-5) was noted for 43% and 12% of the cohort, respectively.

Demographic, clinical and genetic features of the UTUC cohort stratified by UroSEEK results.

	n	%	Ten-gene multiplex positive	TERT positive	Aneuploidy positive	UroSEEK positive

CKD, chronic kidney disease.

[1091] Tumors were confined to a single site along the upper urinary tract in the majority of cases (38% renal pelvis; 39% ureter), while multifocal tumors affecting both renal pelvis and ureter occurred in 23% of the patients. Synchronous bladder cancer (diagnosed within 3 months prior to nephroureterectomy) was present in 38%. Histologically, 89% of the tumors were classified as high grade, with the majority categorized as muscle- invasive (T2-T4, 66%).

Mutational analysis – UTUC Cohort

[1092] Three separate tests were performed for genetic abnormalities that might be found in urinary cells derived from UTUCs (Fig. 32, Table 29, Table 30, Table 31, and Fig. 33). First, mutations were evaluated in selected exomic regions of ten genes (CDKN2A, ERBB2, FGFR3, HRAS, KRAS, MET, MLL, PIK3CA, TP53, and VHL) that are frequently altered in urologic tumors (Sfakianos et al., 2015). For this purpose, a specific set of multiplex primers were designed that allowed detection of mutations in as few as 0.03% of urinary cells (Table 40). The capacity to detect such low mutant fractions was a result of the incorporation of molecular barcodes in each of the primers, thereby substantially reducing the artifacts associated with massively parallel sequencing. Second, *TERT* promoter mutations were evaluated, based on prior evidence that *TERT* promoter mutations are often found in UTUCs. A singleplex PCR was used for this analysis because the unusually high GC-content of the *TERT* promoter precluded its inclusion in the multiplex PCR design. Third, the extent of aneuploidy was evaluated using a technique in which a single PCR is used to co-amplify ~38,000 members of a subfamily of long interspersed nucleotide element-1 (L1 retrotransposons). L1 retrotransposons, like other human repeats, have spread throughout the genome via retrotransposition and are found on all 39 non-acrocentric autosomal arms.

[1093] The multiplex assay detected mutations in 36 of the 56 urinary cell samples from UTUC patients (64%, 95% CI 51 % to 76% (Table 29). A total of 57 mutations were detected in nine of the ten target genes (Fig. 34). The median mutant allele frequency (MAF) in the urinary cells was 5.6% and ranged from 0.3% to 80%. The most commonly altered genes were TP53 (58% of the 57 mutations) and FGFR3 (16% of the 57 mutations) (Table 18). None of the 188 urinary cell

samples from healthy individuals had a detectable mutation in any of the ten genes assayed (100% specificity, CI 97.5% to 100%).

[1094] Mutations in the *TERT* promoter were detected in 16 of the 56 urinary cell samples from UTUC patients (29%, 95% CI 18% to 42%) (Table 30). The median *TERT* MAF in the urinary cells was 2.22% and ranged from 0.59% to 46.3%. One of the 188 urinary samples from healthy individuals harbored a mutation (*TERT* g.1295250C>T with a MAF of 0.39%). In the UTUC urinary cell samples, mutations were detected in three positions: 94% of the mutations were at hg1295228 (67%) and hg1295250 (28%), which are 69 and 91 bp upstream of the transcription start site, respectively. These positions have been previously shown to be involved in the appropriate transcriptional regulation of *TERT*. In particular, the mutant alleles recruit the GABPA/B1 transcription factor, resulting in the H3K4me2/3 mark of active chromatin and reversing the epigenetic silencing present in normal cells.

Aristolochic acid exposure in the UTUC Cohort

[1095] The activated metabolites of aristolochic acid bind covalently to the exocyclic amino groups in purine bases, with a preference for dA, leading to characteristic A>T transversions. To determine whether the individuals in the cohort had been exposed to AA, renal cortical DNA adducts were qualified using mass spectrometry. All but two of the 56 patients had detectable aristolactam (AL)-DNA adducts with levels ranging from 0.4 to 68 dA-AL adducts per 108 nucleotides. Moreover, the A>T signature mutation associated with AA was highly represented in the mutational spectra of TP53 (18/32 A>T) and HRAS (2/2 A>T) found in urinary cells (Table 30).

Aneuploidy analysis in the UTUC Cohort

[1096] Aneuploidy was detected in 22 of the 56 urinary cell samples from UTUC patients (39%, 95% CI 28% to 52%, Table 31, and Fig. 33) but in none of the 188 urinary cell samples from healthy individuals. The most commonly altered arms were 1q, 7q, 8q, 17p, and 18q. Some of

these arms harbor well-known tumor oncogenes or suppressor genes that have been shown to undergo changes in copy numbers in many cancers (Vogelstein et al., 2013).

Comparison with primary tumors – the UTUC Cohort

[1097] Tumor samples from all 56 patients enrolled in this study were available for comparison and were studied with the same three assays used to analyze the urinary cell samples. This comparison served two purposes. First, it allowed determining if the mutations identified in the urinary cells were derived from the available tumor specimen from the same patient. There were a total of 39 UTUC cases in which a mutation could be identified in the urinary cells. In 35 (90%) of these 39 cases, at least one of the mutations identified in the urine sample (Table 29 and Table 30) was also identified in the corresponding tumor DNA sample (Table 32 and Table 33). When all 80 mutations identified in the urinary cells were considered, 63 (79%) were identified in the corresponding tumor sample (Table 32 and Table 33). In any of the three assays, the discrepancies between urine and tumor samples might be explained by the fact that only one tumor per patient was accessible, even though more than one anatomically distinct tumor was often evident clinically. Additionally, DNA was extracted from only one piece of tissue from each tumor, and intratumoral heterogeneity could have been responsible for some of the discrepancies.

[1098] The tumor data helped determine why 17 of the 56 urinary cell samples from UTUC patients did not contain detectable mutations. The reason could either have been that the primary tumors did not harbor a mutation present in the gene panel or that the primary tumor did contain such a mutation but the fraction of neoplastic cells in the urine sample was not high enough to allow its detection. From the evaluation of the primary tumor samples, it was found that four (24%) of the 17 urine samples without detectable mutations were from patients whose tumors did not contain any of the queried mutations (Table 32). The conclusion was that the main reason for failure of the mutation test was an insufficient number of cancer cells in the urine, and this accounted for 13 (76%) of the 17 failures.

[1099] There were 22 cases in which aneuploidy was observed in the urinary cell samples. Overall, 96% of the chromosome gains or losses observed in the urinary cells were also observed in the primary tumors (examples in Fig. 35). Conversely, there were 34 cases in which

aneuploidy was not observed in the urinary cell samples. Evaluation of the 56 tumors with the same assay showed that all but three were aneuploid, so as with mutations, the main reason for failure of the aneuploidy assay was insufficient amounts of neoplastic DNA in the urinary cells.

Biomarkers in combination – the UTUC Cohort

[1100] There are two factors that can limit sensitivity for genetically-based biomarkers. First, a sample can only be scored as positive for the biomarker if it contains DNA from a sufficient number of neoplastic cells to be detected by the assay. Second, the tumor from which the neoplastic cells were derived must harbor the genetic alteration that is queried. Combination assays can increase sensitivity by assessing more genetic alterations, and are thereby more likely to detect at least one genetic alteration present in the tumor. However, mutations in clinical samples often are present at low allele frequencies (Table 29 and Table 30), requiring high coverage of every base queried. It would be prohibitively expensive to perform whole exome sequencing at 10,000x coverage. In this study, the selected regions of 11 genes (including *TERT*) were carefully evaluated together with copy number analysis of 39 chromosome arms. Even if a tumor does not contain a genetic alteration in one of the 11 genes assessed, it might still be aneuploid and detectable by the urinary cell assay for aneuploidy. The sensitivity of aneuploidy detection is less than that of the mutation assays. Simulations showed that DNA containing a minimum of 1% neoplastic cells is required for reliable aneuploidy detection, while mutations present in as few as 0.03% of the DNA templates can be detected by the mutation assays used in this study. Nevertheless, urinary cell samples that had relatively high fractions of neoplastic cells but did not contain a detectable mutation in the 11 queried genes should still be detectable by virtue of their aneuploidy because, as noted above, 53/56 UTUCs studied here were aneuploid. Additionally, some of the mutations in the 11 genes queried, such as large insertions or deletions or complex changes, might be undetectable by mutation-based assays but a sample with such an undetectable mutation could still score positive in a test for aneuploidy.

[1101] To determine whether these theoretical arguments made a difference in practice, biomarker performance was evaluated with the combined approaches, collectively called UroSEEK. As noted above, the ten-gene multiplex assay, the *TERT* singleplex assay, and the aneuploidy assays yielded 64, 29%, and 39% sensitivities, respectively, when used separately.

Twenty-three samples without *TERT* promoter mutations tested positive for mutations in one of the other ten genes (Venn diagram in Fig. 32). Conversely, three samples without detectable mutations with the multiplex assay scored positive for *TERT* promoter mutations (Fig. 32). And, three of the urinary cell samples without any detectable mutations were positive for aneuploidy (Fig. 32). Thus, when the three assays were used together, and a positive result in any one assay was sufficient to score a sample as positive, the sensitivity rose to 75% (95% CI 62.2% to 84.6%). Only one of the 188 samples from healthy individuals scored positive in the UroSEEK test (specificity 99.5%, CI 97.5 to 100%).

[1102] To determine the basis for the increased sensitivity afforded by the combination assays, data from the primary tumors of the three patients whose urinary cell samples exhibited aneuploidy but did not harbor detectable mutations were evaluated. It was found that these three tumors did not contain any mutations in the 11 queried genes, explaining why these same assays were negative when applied to urinary cell DNA. As noted above, these three tumors were aneuploid, thus affording the opportunity to detect these copy number variations in the urinary cell samples.

Correlation with clinical features

[1103] A cancer biomarker should advantageously be able to detect tumors at an early stage, enabling surgical removal of the lesions prior to widespread metastasis. UroSEEK was sensitive in detecting both early and late tumors. It scored positive in 15 (79%) of 19 patients with stage Ta or T1 tumors and in 27 (73%) of 37 patients with stage T2-T4 tumors. Ten-year cancer specific survival rates show that 91% of UTUC patients with stage T1 malignancies are expected to be cured by surgery, compared to only 78%, 34% and 0% of patients with stage 2, 3, or 4 tumors, respectively.

[1104] UroSEEK sensitivity was independent of a variety of clinical parameters other than tumor stage, including gender, CKD stage, tumor grade, tumor location and risk factors for developing UTUC, indicating that the assay is suitable for evaluation of diverse patient populations. Furthermore, UroSEEK was considerably more sensitive than urine cytology in this cohort. Cytology was available in 42 cases, and of these only four (9.5%) were diagnosed as carcinoma cytologically. Even if samples scored as “suspicious for malignancy” by cytology were

considered as positive, the sensitivity was only 26% (including the four scored as positive and seven scored as suspicious). UroSEEK detected all four cases scored as positive by cytology, five of the seven cases scored as suspicious for malignancy, and 22 of the 31 samples scored by cytology as inconclusive or negative.

Example 6: Detection of aneuploidy in patients with cancer through amplification of long interspersed nucleotide elements (LINEs)

[1105] This Example describes a new approach for amplicon-based aneuploidy detection. This approach, called WALDO for **W**ithin-**S**ample-**A**neup**L**oidy-**D**etecti**O**n (WALDO), employs supervised machine learning to detect the small changes in multiple chromosome arms that are often present in cancers. It is shown herein that WALDO can be applied to identify chromosome arm gains or losses with improved sensitivity and equivalent specificity compared to previous approaches. Furthermore, machine learning can be incorporated to make genome-wide aneuploidy calls, in which samples are classified according to their aneuploidy status. This Example reports WALDO results on thousands of samples, including tissues of ten different tumor types as well as liquid biopsies of plasma from cancer patients. When two samples are available for comparison, WALDO can be used to assess genetic relatedness or to find somatic mutations within the LINEs. Thus, this approach can be used to provide an estimate of somatic mutation load, evaluate carcinogen signatures, and detect microsatellite instability (Fig. 1).

Materials and Methods

Samples

[1106] A total of 1,678 tumors were evaluated in this study (see below).

Sample Source	Sample Type	Number of Samples	Number of Samples Including Replicates	Matched Normal	Mutation Data
Peripheral white-blood-cell (WBC)	Normal	176	677	N/A	No

Tumor	Breast Invasive Carcinoma (BRCA)	45	45	No	No
Tumor	Colon Adenocarcinoma and Rectum Adenocarcinoma (COAD;COADREAD)	536	536	No	No
Tumor	Colorectal Adenoma	32	32	N/A	No
Tumor	Esophageal Carcinoma (ESCA)	42	42	No	No
Tumor	Head and Neck Squamous Cell Carcinoma (HNSC)	96	96	No	No
Tumor	Liver Heptaocellular Carcinoma (LIHC)	56	56	No	No
Tumor	Ovarian Serous Cystadenocarcinoma (OV)	157	157	No	No
Tumor	Pancreatic Adenocarcinoma (PAAD)	345	345	No	No
Tumor	Stomatic Adenocarcinoma (STAD)	28	28	No	No
Tumor	Uterine Corpus Endometrial Carcinoma (UCEC)	296	296	No	No
Tumor (Cell Line)	Mismatch Repair Deficient Colorectal Carcinoma	6	6	Yes	No
Plasma	Normal	402	566	N/A	No
Plasma	Pancreatic Adenocarcinoma (PAAD)	547	547	No	Yes
Plasma	Breast Invasive Carcinoma (BRCA)	28	28	No	Yes
Plasma	Colon Adenocarcinoma and Rectum Adenocarcinoma (COAD;COADREAD)	167	167	No	Yes
Plasma	Esophageal Carcinoma (ESCA)	17	17	No	Yes
Plasma	Liver Heptaocellular Carcinoma (LIHC)	54	54	No	Yes
Plasma	Stomatic Adenocarcinoma (STAD)	16	16	No	Yes
Plasma	Ovarian Serous Cystadenocarcionma (OV)	14	14	No	Yes
Plasma	Lung	113	113	No	Yes

[1107] The number of cancers of each histopathologic subtype are listed in the Appendices. The tumors were formalized fixed and paraffin-embedded (FFPE). In all cases, DNA was purified using QIAsymphony (cat # 937255). Peripheral white blood cells (WBCs) were purified from the blood of 176 healthy individuals. Plasma was purified from 566 healthy individuals and 982 patients with cancer. DNA was purified from WBCs and plasma using Qiagen kit numbers (cat # 1091063) and (cat # 937255) respectively. The majority of the plasma samples used in this study

has been independently evaluated for mutations in one of twelve commonly mutated genes. The fraction of mutant alleles in these plasma samples was used as an estimate of their neoplastic cell content. All individuals participating in the study provided written informed consent after approval by the institutional review boards of the hospitals at which they were collected.

Fast-SeqS

[1108] For each DNA sample evaluated, FAST-SeqS was used to amplify approximately 38,000 amplicons with a single primer pair (Kinde et al., 2012 *PloS ONE* 7:e41162). Massively parallel sequencing was performed on Illumina instruments (HiSeq 2500, HiSeq 4000, or MiSeq). During amplification, degenerate bases at the 5' end of the primer were used as molecular barcodes to uniquely label each DNA template molecule as described elsewhere (see, e.g., Kinde et al., 2011 *Proceedings of the National Academy of Sciences* 108:9530-9535). This ensured that each DNA template molecule was counted only once. In all instances in this paper, the term "reads" refers to uniquely identified reads. Depending on the experiment, each read was sequenced between 1 and 20 times. For each WBC and tumor DNA sample, 100,000 to 25 million reads were used for analysis. For each plasma DNA sample, 100,000 to 15 million reads were used. Replicates of normal DNA were included in every sequencing experiment and used to evaluate stochastic and experimental variability.

Sample alignment and genomic interval grouping

[1109] Bowtie2 was used to align reads to human reference genome assembly GRC37. 37,669 exact matches (33,844 excluding the sex chromosomes) to the reference genome were identified. These exact matches allowed inclusion of common polymorphisms. The polymorphisms included 24,720 single nucleotide polymorphisms (SNPs) and 1,500 insertion and deletion (indel) polymorphisms, with minor allele frequencies were >1% in the1000 Genomes database (Consortium 2012 *Nature* 491:56-65).

[1110] In light of experimental and stochastic variation, the number of reads that mapped to each genomic region of any euploid sample was expected to be variable. To minimize this variability,

clusters of 500-kb genomic intervals with similar read depth across all chromosomes in *multiple euploid samples* were identified. This step permitted estimation of the expected variability in read depth in a sample when no aneuploidy was present. Genomic intervals smaller and larger than 500 kb were tested, and it was found that 500 kb yielded reasonable performance in the assays described below at reasonable computational expense.

[1111] Clustering of the 500-kb genomic intervals was performed as follows. Each test sample was matched to euploid samples that had similar amplicon sizes. This was done because smaller amplicons will be over-represented in the amplicons generated from DNA that is of small size prior to amplification. The size of the amplicons generated by FastSeqS range from 100 to 140 bp (Kinde et al., 2012 *PloS ONE* 7:e41162). The size of plasma DNA is 140 to 180 bp (Diehl et al., 2005) *Proceedings of the National Academy of Sciences of the United States of America* 102:16368-16373; Chan et al., 2004 *Clinical chemistry* 50:88-92; Jahr et al., 2001 *Cancer research* 61:1659-1665; and Giacona et al., 1998 *Pancreas* 17:89-97), so the largest LINE amplicons will be substantially underrepresented in plasma DNA compared to WBC DNA, for example. It was found that seven euploid samples was sufficient for comparison to any test sample; using more than seven euploid samples did not substantially increase performance. The seven euploid samples were derived from a collection of 677 WBC or 566 plasma DNA from normal individuals, collectively termed the "euploid reference set". For each test sample p, the seven normal samples with the smallest Euclidean distance to p were selected, defined as $D(p,q)=\sqrt{\sum_n (q_n - p_n)^2}$ where, p_n and q_n are the fraction of amplicons of size n in samples p and q, and the sum is over all amplicon sizes in the two samples. Before calculating the Euclidian distances between the test samples from the samples in the euploid reference set, the following amplicons were excluded: (i) Using maximum likelihood estimates, the amplicons were ranked by variance among the seven euploid samples and the top 1% excluded. (ii), any amplicons with < 10 reads in one sample but > 50 reads in any of the other six samples were removed. In each sample, the 500-kb genomic intervals were scaled by subtracting the mean and dividing by the standard deviation of reads in each sample.

[1112] The scaled 500-kb genomic intervals were then clustered across the seven selected normal samples in the following way. First, each 500-kb genomic interval i was assigned to a primary cluster C_i. Next, the reads in genomic interval i across all samples was compared to the average number of read in the seven samples in all other genomic intervals i' that occurred on

the remaining 21 autosomal chromosomes. Insignificant results (paired t-test $p>0.05$, f-test $p>0.05$) were tested fro during the search for similarity. If the average number of reads in genomic interval *i'* was not significantly different from the number of reads in genomic interval *i*, it was added to cluster C_i. This process was repeated for each of the 4361 genomic intervals, yielding 4361 clusters. Every interval *i* belonged to its primary cluster but the same interval also belonged to an average of 176 other clusters (range of 100 to 252 clusters among 190 representative samples). The number of unique clusters was less than the 4361 because some clusters were composed of the same 500-kb genomic intervals. The number of unique clusters was typically 4310 to 4330 among 190 representative samples. Clusters contained an average of approximately two hundred 500-kb genomic intervals (see Fig. 45). Scaled reads were not randomly distributed (see Fig. 46A). However, the distribution of scaled reads within the ~200 genomic intervals in each cluster followed an approximately normal distribution (example in Fig. 46B-C).

Identifying chromosome arm gains or losses in a test sample

[1113] WALDO used the seven euploid samples described above *only* to define clusters of genomic intervals with similar amplification properties. The statistical tests for aneuploidy in WALDO were based on the read distributions *within* the test sample and independently of the read distributions in any euploid sample. For a test sample, maximum likelihood was used to estimate the means μ and variances σ^2 of the genomic intervals in each of the 4,361 clusters defined by the seven euploid samples that were chosen to match it on the basis of amplicon length. The robustness of these estimates was improved by iteratively removing outlying genomic intervals within the test sample from the clusters. Clusters containing fewer than 10 genomic intervals were not included in the analysis. For each cluster, any 500-kb genomic interval meeting the criteria $min(\ 2*\ CDF(\mu,\ \sigma_i^2),\ 2*(1-CDF(\mu,\ \sigma_i^2)\ ) < 0.01$ was removed from all clusters. Next, the μ and σ^2 parameters of each cluster were re-estimated by maximum likelihood. The two steps were repeated until no outlying genomic intervals remained. The statistical significance of the total reads was then estimated from all 500-kb genomic intervals on the arm. Because sums of normally distributed random variables are also normally distributed

random variables, the calculation was straightforward (see Fig 47). For each chromosome arm, $\sum_1^I R_i \sim N(\sum_1^I \mu_i, \sum_1^I \sigma_i^2)$ was calculated, where Ri is the scaled reads and I is the number of clusters on the arm. Z-scores were produced using the quantile function 1-CDF($\sum_1^I \mu_i, \sum_1^I \sigma_i^2$). Positive Z-scores > α represented gains and negative Z-scores < -α represented losses, where α was the selected significance threshold.

Arm level allelic imbalance

[1114] Common polymorphisms from 1000 Genomes (24,720 single nucleotide and 1,500 indels, MAF>1%) were used as candidate heterozygous sites. For each of the 677 normal samples, polymorphic sites were identified that could be confidently called as heterozygous and diploid. Polymorphisms were defined as those with variant-allele frequencies (VAF) (0.4<VAF<0.6), where VAF = #non-reference reads / total reads. VAFs were modeled at these sites as random variables taken from a normal distribution with μ=0.5; the variance σ^2 was estimated by maximum likelihood as a function of read depth (Fig. 48). To determine whether the alleles on a chromosome arm in a test sample were unbalanced, the subset of polymorphic sites was identified at which both alleles were present and in which the sum of the reads on both alleles was >25. The observed VAF was then compared with the normal distribution, using the expected variance for the observed read depth, yielding a two-sided P-value. All p-values on a chromosome arm were Z-transformed and combined with a weighted Stouffer's method, with the observed read depth at each site used as its weight. The formula used for this calculation was $Z \sim \frac{\sum_{i=1}^k w_i Z_i}{\sqrt{\sum_{i=1}^k w_i^2}}$, where w_i is UID depth at variant i, Z_i is the Z-score of variant i, and k is the number of variants observed on the chromosome arm. A chromosome arm was scored as having an allelic imbalance if the resulting Z score was greater than the selected statistical significance threshold α (one-sided test).

Generation of synthetic aneuploid samples

[1115] Data from 63 presumably euploid samples was selected, each containing at least 9 million reads, and each derived from the DNA of normal WBCs. Synthetic aneuploid samples were created by adding (or subtracting) reads from several chromosome arms to the reads from these normal DNA samples. Reads from 1, 5, 10, 15, 20, or 25 randomly selected chromosome arms were added to or subtracted from each sample. The additions and subtractions were designed to represent neoplastic cell fractions ranging from 0.5% to 10% and resulted in synthetic samples containing exactly nine million reads. The reads from each chromosome arm was added or subtracted uniformly. For example, when five chromosome arms that were lost were modeled, each was lost to the identical degree and we did not incorporate tumor heterogeneity into the model. Furthermore, synthetic samples containing two or more of the same extra chromosome arms were not created, such as synthetic cells containing 4 copies of chromosome 3p. This simplified approach did not comprehensively cover all biologically plausible aneuploidy events. However, limiting the possible combinations of altered arms made sample generation computationally tractable, and the resulting support vector machine worked well in practice.

[1116] The synthetically generated samples in which reads from only a single chromosome arm were added or subtracted enabled us to estimate the performance of WALDO when only a single chromosome arm of interest was gained or lost. The synthetic set in which 5-25 chromosome arms were altered permitted assessment of the performance of WALDO in typical samples derived from cancers. As shown in Fig. 37, most cancers have gains or losses of multiple chromosomes. The algorithms used to generate the synthetic samples are shown as pseudocode in Fig.49 and Fig. 50.

Genome-wide aneuploidy detection

[1117] A two-class support vector machine (SVM; Cortes 1995 *Machine learning* 20:273-297) was trained to discriminate between euploid samples and the synthetic samples in which the reads from 5 to 25 chromosome arms were added or subtracted. The training set contained 677

WBC negative samples (presumably euploid WBCs containing 3 million -15 million reads) and 3150 positive samples, all synthetic as described above. SVM training was done with the e1071 package in R, using radial basis kernel and default parameters (Meyer et al., 2015 *R package version*:1.6-3). Each sample had 39 Z-score features, representing chromosome arm gains and losses. 677 synthetic samples were randomly sampled so that the sizes of the negative and positive classes were equivalent, and this was repeated ten times. Each sample to be classified was scored by all ten SVMs, and the ten scores were averaged to yield a final score.

[1118] The number of reads from the data on experimental samples can vary widely, particularly when the samples are derived from sources with limited amounts of DNA such as plasma. Samples with low reads can generate artificially high SVM scores if read depth is not taken into account. Read depth was therefore controlled for by modeling the change in SVM scores as a function of read depth in the normal samples. In particular, each of the 63 WBC euploid samples was randomly down-sampled to yield ten replicates of lower read euploid samples of read depth ranging from 100,000 to 9 million. All down-sampled euploid samples were scored using the 10 SVMs were and the scores were averaged. This procedure yielded 630 SVM scores for the down-sampled euploid samples at each read depth. All scores were converted to ratios by finding the sample at each read depth with the minimum SVM score and dividing all scores at the same depth by that value. The average ratio r at each depth decreased monotonically as a function of increasing read depth (Fig. 51). The relation between read depth and SVM score was modeled using the following equation (A=-7.076*10^-7 and B = -1.946*10^-1). Raw SVM scores were corrected by dividing by the ratio r, using the formula $\log\left(1-\frac{1}{r}\right) = Ax + B$.

[1119] To score a sample as aneuploid, it was first determined whether any single chromosome arm in it was lost or gained in a statistically significant manner. A statistically significant gain of a single chromosome arm was defined as one whose Z-score was >4 $^{\sigma}$ above the maximum Z-score observed in the 677 normal WBC samples. Similarly, a statistically significant loss of a single chromosome arm was defined as one whose Z-score was <-4 $^{\sigma}$ below the minimum Z-score observed in the 677 normal WBC samples. Allelic imbalance based on SNPs was defined for a chromosome arm whose Z-score was Z-score was >4 $^{\sigma}$ above the maximum Z-score observed in the 677 normal WBC samples. Only samples in which no single chromosome arm was gained or lost when defined in this way were subjected to SVM analysis. The rationale for

this process was that the SVM was designed to identify samples with large numbers of chromosome arm gains or losses but relatively low neoplastic cell fractions. The SVM was not designed to detect aneuploidy in samples with neoplastic cell fractions >10%, which were easily identified through evaluation of their Z-scores and comparison to the 677 normal samples as described in the first part of this paragraph.

Somatic sequence mutations and microsatellite instability (MSI)

[1120] When matched normal samples were available, it was attempted to detect somatic single base substitution (SBS), insertion and deletion (indel) mutations based on LINE amplicon sequences and alignments. In such cases, the molecular barcoding approach for error reduction was used. For SBS, only amplicons that have at least 200 reads and 50 unique molecular barcodes were considered. For indels, reads that were observed in at least two clusters on the sequencing instrument were considered. The SBS mutations were identified by directly comparing amplicons from the test sample with amplicons from the matched normal, and did not require any alignment to the reference genome. Amplicons with fewer than 50 reads in the matched normal sample were excluded. A somatic SBS was defined as one in which at least five reads from the test sample differed from any normal read by exactly one nucleotide substitution.
[1121] Indels were called in a similar way. Amplicons from the test sample and matched normal sample to were first aligned the reference genome (GRc37) with Bowtie2 (Langmead 2012 *Nature Methods* 9:357-359). A somatic indel was defined as one in which at least ten reads from the test sample differed from any normal read by virtue of the same insertion or deletion.
[1122] Microsatellite instability in a test sample was determined by counting the number of somatic indels in mononucleotide tracts of > 3 nucleotides. There were 17,488 of these mononucleotide tracts in the LINE amplicons that were studied. It was expected that somatic indels in monotracts would be rare in a normal sample. Therefore, the null distribution of counts could be modeled as Poisson ($\lambda = 1$), where λ is the mean number of somatic indels in a monotract in a normal sample. A sample was called as harboring MSI if the number of somatic indels was statistically significant. To evaluate how often normal samples would be scored as MSI using this process, the total reads in normal samples was randomly split into two equal

partitions. The first partition was used as the reference sample and the second partition was used as a test sample.

Sample matching

[1123] To compare one sample to another, amplicons were first aligned to the reference genome GRC37 with Bowtie2. The 1000 Genomes common polymorphisms were used to identify the genotypes at 26,220 sites in each sample. Each polymorphic site was called as "0" (homozygous reference, >0.95 reads matching reference allele, minimum of ten reads), "1" (heterozygous, 0.05-0.95 UIDS matching either reference or alternate allele, minimum of ten reads of each allele), or "2" (homozygous alternate, >0.95 UIDs matching alternate allele, minimum of ten reads). Concordance was defined as the number of matched polymorphic sites that were identical in both samples (i.e., were both "0", both "1", or both "2") divided by the total number of genotypes that had adequate coverage in both samples. Two samples were considered a match if concordance was > 0.98 and at least 15,000 amplicons had adequate coverage.

TCGA somatic copy number alterations

[1124] The most recent Cancer Genome Atlas Level 4 somatic copy number alteration files from Firehose were downloaded (Aggregate_AnalysisFeatures.Level_4.2016 012800.0.0), from GISTIC analysis (Beroukhim et al., 2007 *Proceedings of the National Academy of Sciences* 104:20007-20012) of Affymetrix SNP6 arrays. 9 TCGA tumor types were selected that matched our cohorts of primary tumor samples (Breast invasive carcinoma (BRCA), colon adenocarcinoma (COAD), colon or rectal adenocarcinoma (COADREAD), esophageal carcinoma (ESCA), head and neck squamous cell carcinoma (HNSC), liver hepatocellular carcinoma (LIHC), ovarian serous cystadenocarcinoma (OV), pancreatic adenocarcinoma (PAAD), stomach adenocarcinoma (STAD), and uterine corpus endometrial carcinoma (UCEC)). A total of 6276 samples were available (Breast invasive carcinoma (BRCA):1081, colon adenocarcinoma, colon or rectal adenocarcinoma (COAD;COADREAD): 2755, esophageal carcinoma (ESCA): 185, head and neck squamous cell carcinoma (HNSC): 523, liver

hepatocellular carcinoma (LIHC): 371, ovarian serous cystadenocarcinoma (OV): 580, pancreatic adenocarcinoma (PAAD): 185, stomach adenocarcinoma (STAD): 442, uterine corpus endometrial carcinoma (UCEC): 540). The data consisted of GISTIC $\log_2$ ratios representing gains or losses of each chromosome arm (Mermel et al., 2011 *Genome biology* 12:R41). Ratios > 0.2 or < 0.2 were considered gains or losses (Laddha et al., 2014 *Molecular cancer research* 12:485-490).

Comparison with a prior technique for detecting single chromosome arm alterations

[1125] The fraction of reads that mapped to each chromosome arm in each of the 677 WBC samples, and their averages and standard deviations, were calculated (Kinde et al., 2011 *Proceedings of the National Academy of Sciences* 108:9530-9535). The score for each arm was computed as: $z_{i,chrN} = (chrN_i - \mu_{chrN}) / \sigma_{chrN}$, where $chrN_i$ represents the normalized read counts for that chromosome arm and μ_{chrN} and σ_{chrN} represent the mean and standard deviation of the normalized reads counts.

Results

Statistical principles underlying WALDO

[1126] Unlike most conventional approaches for assessing copy number changes, WALDO does *not* compare normalized read counts from each chromosome arm in a test sample to the fraction of reads in each chromosome arm in other samples. Such conventional comparisons are subject to batch effects and other artifacts associated with variables that are difficult to control. To evaluate whole genome sequencing data, aneuploidy was detected by comparing the read counts of LINEs within 4361 genomic intervals each containing 500-kb of sequence. The read counts within the 500-kb genomic intervals within a sample were only compared to the read counts of other genomic intervals within the *same* sample - hence the "Within-Sample" designation in WALDO.

[1127] In euploid samples, the number of LINE reads within each 500-kb genomic interval should track with the number of reads in certain other genomic regions. Genomic intervals that

track together do so because the amplicons within them amplify to similar extents. Here, such genomic regions that track together are called "clusters". It is possible identify clusters from sequencing data on euploid samples. In a test sample, it is determined whether the number of reads in each genomic interval in each pre-defined cluster is within the expected bound of the other clusters from that same sample. If the reads within a genomic interval are outside the statistically expected bound, and there are many such outsiders on the same chromosome arm, then that chromosome arm is classified as aneuploid. The statistical basis of this test is described in the Materials and Methods. In brief, while the number of reads at each LINE is not randomly distributed across the genome, the distribution of scaled reads within each cluster is approximately Normal. A convenient property of Normal distributions is that the sum of multiple Normal distributions is also a Normal distribution. It is thus possible to compute the theoretical mean and variance of the summed reads on each chromosome arm simply by summing the means and variances of all the clusters represented on that chromosome arm.

[1128] WALDO also employs several other innovations that make it applicable to the analysis of PCR-generated amplicons from clinical samples. One of these innovations is controlling amplification bias stemming from the strong dependence of the data on the size of the initial template. Another is the use of a Support Vector Machine (SVM) to enable the detection of aneuploidy in samples containing low neoplastic fractions. The conceptual and statistical bases for WALDO are detailed in the Materials and Methods section herein.

Evaluation of chromosome arm gains and losses in primary tumor samples

[1129] WALDO was first used to study chromosome arm gains and losses in 1,677 primary tumor samples from ten cancer types. One of the outputs of WALDO is a z-score for each of the 39 non-acrocentric arms on the autosomal chromosomes. The z-scores for each of these chromosome arms in each of the primary tumor samples evaluated in this study are provided in Table 35. These results were compared with those obtained by The Cancer Genome Atlas (TCGA) on independent samples of the same tumor types (Zack et al., 2013 *Nature genetics* 45:1134-1140; and Beroukhim et al., 2007 *Proceedings of the National Academy of Sciences* 104:20007-20012). The fraction of tumor samples having a gain or a loss in each chromosome arm was identified in our data and in TCGA, considering all tumor types together and each

tumor type individually. As shown in the top half of Fig. 37, the fraction of samples in all cancer types scored as a gain by WALDO or as a gain by TCGA's algorithm (GISTIC) is shown for each chromosome arm, and the fraction of samples with a loss is shown in the bottom half. The correlations between arm-level gains scored in this study and those in TCGA are shown in Fig. 39A (R^2=0=45) and arm-level losses are shown in Fig. 39B (R^2=0.39). Considering that the samples were from completely different patients, the specific chromosome arms gained and lost in both datasets were remarkably similar. The chromosome arms with the most gains were 1q, 3q, 7p, 7q, 8q, and 20q and relatively few losses were observed on these arms. Those with the most losses were 4p, 4q, 8p, and 18q and relatively few gains were observed on these arms. The arms with fewest gains or losses were 10p, 16p, 19p, and 19q.

[1130] Similarly high correlations were observed for many of the specific tumor types in those cases in which a sufficient number of cancers were available for comparison (see below, and Fig. 40).

	Gain Correlation	Loss Correlation	WALDO Samples	GISTIC Samples
BRCA	0.629	0.436	89	181
COAD;COADREAD	0.582	0.428	536	2755
ESCA	0.043	0.07	42	185
HNSC	0.537	0.344	96	523
LIHC	0.64	0.287	56	371
OV	0.067	0.123	157	580
PAAD	0.384	0.702	345	185
STAD	0.552	0.555	28	442
UCEC	0.325	0.165	296	540

[1131] The highest correlations were for pancreatic adenocarcinomas and liver cancers (R^2=0.70 and R^2=0.64, respectively). An interesting outcome of this analysis was the large number of chromosome arms that were aneuploid in the great majority of cancer cases. The median number of chromosome arms that were lost or gained per cancer was 14, with interquartile range of 5 to 22. This large number was used for the development of the Support Vector Machine described below.

[1132] 32 benign tumors of the colon (colorectal adenomas) were also evaluated. It was found that 25 of them displayed gains or losses of chromosomes. The median number of chromosome arms that were lost or gained per benign tumor was 4, with interquartile range of 1 to 9.75. No benign tumors have yet been studied by TCGA, so comparison was not possible. However, comparison to colorectal cancers showed that the benign tumors had many fewer chromosome arm changes than observed in cancers. Additionally, the chromosome arms altered in the adenomas overlapped with those in the cancers, and the directionality of the changes (gains *vs.* losses) was preserved.

[1133] WALDO also allows determination of allelic imbalances based on the SNPs with the LINEs that are concomitantly sequenced. This provides a totally independent measure of chromosome arm changes than provided by the number of reads across the 500-kb genomic intervals. Note that measurements of allelic imbalance represent the ratios between the number of reads of the reference allele vs. those of the variant allele. This ratio will be the same whether the chromosome arm containing the reference allele is gained or the arm containing the variant allele is lost. Nevertheless, without wishing to be bound by theory, one would expect that there would be a strong relationship between the chromosomes exhibiting allelic imbalances and those exhibiting either gains or losses in the same tumor. It was found that 63% of chromosome arms with allelic imbalance also had a significant gain or loss at the same chromosome arm. Other uses of the SNPs within the LINEs are described herein.

[1134] Next, the sensitivity and specificity of WALDO to call single chromosome arm gains or losses was compared (see Materials and Methods). Both methods were applied to LINE amplicon sequencing data from 677 normal peripheral white blood cell (WBC) samples, with each WBC sample independently amplified and sequenced to an average depth of 9.5M reads. This experimental data was augmented by 24,570 synthetic samples with single chromosome alterations (see Materials and Methods). Sensitivity was computed as the total number of correctly identified altered arms divided by the total number of altered arms in the synthetic samples. Specificity was computed as 1 minus the total number of incorrectly called altered arms divided by the total number of normal arms in the experimental data from the normal WBC samples. For both WALDO and the previous method, three significance thresholds (± 1.96, ± 3.0, ± 5.0) and three neoplastic cell fractions (1%, 5%, 10%) were considered. For all thresholds

and neoplastic cell fractions, WALDO had higher specificity and sensitivity (see below, and Table 34).

Dilution	Threshold	WALDO Sensitivity	WALDO Specificity	Z Score Sensitivity	Z Score Specificity
0.010	1.96> or <-1.96	0.221	0.969	0.144	0.952
0.010	3> or <-3	0.031	0.999	0.020	0.995
0.010	5> or <-5	0.000	1.000	0.000	1.000
0.050	1.96> or <-1.96	0.969	0.969	0.899	0.952
0.050	3> or <-3	0.917	0.999	0.748	0.995
0.050	5> or <-5	0.671	1.000	0.443	1.000
0.100	1.96> or <-1.96	0.999	0.969	0.988	0.952
0.100	3> or <-3	0.995	0.999	0.957	0.995
0.100	5> or <-5	0.957	1.000	0.839	1.000

[1135] To further evaluate the ability of WALDO to detect single chromosome abnormalities, DNA from patients with trisomy 21 was also evaluated. The DNA from individuals with trisomies were physically mixed at a ratio of 2 ng of normal DNA and 0.2 ng of Trisomy 21 DNA. The mixtures were created to replicate typical fetal fractions in noninvasive prenatal testing (approximately 10%). Using polymorphisms in the LINE amplicons, the trisomy admixture rate of the samples (range 7.7%-10.4%) was estimated. Using a z threshold of 2.5, it was found that as few as 2M reads could detect trisomy 21 at fetal fractions typically observed (Sensitivity 95%). 16 normal WBC were then sampled at various read depths. At 2M reads using the same threshold, the specificity was 100 %. Sensitivities and specificities at other read depths and other admixtures of trisomy 21 samples are summarized in Fig. 41.

Aneuploidy detection in samples with low fractions of neoplastic cell DNA

[1136] Many potential applications of aneuploidy detection in cancer involve identifying a relatively small fraction of DNA from neoplastic cells within a large pool of DNA derived from normal cells. One notable application is liquid biopsy, i.e., the evaluation of bodily fluids such as urine, saliva, cyst fluid, or sputum for evidence of cancer. Given that aneuploidy is a general

feature of cancers of virtually all types (see Fig. 37), detecting aneuploidy could be used for this purpose.

[1137] To employ WALDO for liquid biopsies, a 2-stage approach was used. The first employed a search for individual chromosome arm gains or losses or allelic imbalance, as described above. Simulations with synthetic DNA showed that this approach could detect an individual chromosome arm gain or loss with sensitivities > 90% at specificities >99% when the fraction of DNA contributed by the neoplastic cells was >5% of the total DNA. To detect aneuploidy in samples with lower fractions of neoplastic cell DNA, that fact that the median number of chromosome arm gains or losses per tumor was high (Kinde et al., 2012 *PloS ONE* 7:e41162) was exploited. A variety of approaches to distinguish samples containing low fractions of neoplastic DNA with multiple chromosome abnormalities from euploid samples was therefore considered. These approaches included counting the number of significant arms, combining scores of the most significant arms, and summing squared window-based Z-scores. Based on synthetic samples, it was found that the optimum approach was obtained with a Support Vector Machine (among many machine learning algorithms tested). The Support Vector Machine training was designed to be generally applicable to any cancer type rather than based on patterns of gains and losses typical of specific cancer types. With synthetic samples, the Support Vector Machine could detect aneuploidy in 78% of samples with a neoplastic cell fraction of 1% at a specificity of 99% as determined by cross validation. This Support Vector Machine-based algorithm was therefore incorporated into WALDO for the evaluation of clinical samples with low neoplastic composition (see Fig. 38).

[1138] WALDO was then used to attempt to evaluate aneuploidy in plasma samples from 961 cancer patients and 566 healthy individuals (see Materials and Methods). Cancers of 8 different types were evaluated (see Table 36). The neoplastic cell fraction of each cancer sample was considered to be the mutant allele fractions determined from deep sequencing data. Samples were divided into those with neoplastic cell fractions >1% (122 samples), between 0.5% and 1% (96 samples) and <0.5% (738 samples). Sensitivity was defined as the proportion of cancer patient samples scored as aneuploid, while specificity was defined as 1 minus the fraction of healthy patient samples scored as aneuploid. Receiver operating curves (ROC) are shown in Fig. 38 for these three ranges of neoplastic fractions. At stringent specificity (99%), aneuploidy was identified in 42% of samples with neoplastic cell fractions >1% (see Fig. 38A). As expected,

sensitivity decreased with decreasing neoplastic cell fractions (see Fig. 38B, 38C). At 99% specificity, WALDO detected aneuploidy in 24% of samples with neoplastic cell fractions of 0.5 to 1% and in 19% of samples with neoplastic cell fractions of 0 to 0.5%. The specific cancer type of the patient was not highly correlated with positive aneuploidy calls. However, the number of template molecules that were assessed did correlate with sensitivity.

[1139] In plasma samples with higher neoplastic cell content, it was possible to determine which chromosome arms were gained or lost. Among 558 of the plasma samples that had a paired primary tumor, 188 samples had a significant chromosome arm gain or loss and 54% had a concordant gain or loss in the primary tumor. In samples with low neoplastic content, none of the individual arms were gained or lost at statistically significant levels but the Support Vector Machine component of WALDO was presumably able to pick out small deviations in multiple chromosome arms that distinguished them from euploid samples.

Sample matching

[1140] DNA profiling with short tandem repeats is a well-established forensic technique that is now routinely used. Carefully curated SNP panels have also been developed to ensure sample identity, such as between tumor and normal specimens from the same patients (Kidd et al., 2006 *Forensic science international* 164:20-32; and Pengelly et al., 2013 *Genome medicine* 5:89). The LINEs amplified in FAST-SeqS contain 26,220 common polymorphisms, including variants detected in >1% in 1000 Genomes (Consortium 2012 *Nature* 491:56-65). These polymorphisms theoretically provide a powerful way to profile DNA samples evaluated for aneuploidy without any additional work or cost. To determine whether such identification was possible in practice, a measure of concordance between any two samples was designed (see Materials and Methods). This to measure concordance was then used in replicates of 176 normal WBC samples to one another, using ~5 replicates per sample, for a total of 676 WBC samples. The input to WALDO was 676 samples, without specifying the sample name, so there were a total of 456,976 (676 x 676) possible matches. WALDO correctly matched all replicate samples with high concordance (>99.9%), without any false matching. Next, this protocol was performed on 970 plasma samples and 1,684 tumor samples. The 558 plasma samples should match the corresponding primary tumor samples and no other matches should be observed. This produced 7,038,409 ((970+1,683)

x (970+1,683)) possible matches. Nearly all the 2653 samples matched as expected, i.e., only to themselves or to the corresponding primary tumors, with concordance >99.8%. However, two plasma samples were found that did not match to the expected primary tumors and 12 plasma samples that matched to other plasma samples that were purportedly derived from different donors. In all these "mismatched cases", the FastSeqS data indicated high concordances (>99.8%). The mismatches were therefore most likely a result of mislabeling of the samples and illustrated the utility of sample identity check with WALDO.

Mutation load, carcinogenic signatures, microsatellite instability

[1141] When two samples, a normal and a cancer, are available from the same patient, LINE mutations that are in one sample but not the other can conceivably be discerned. For this application, molecular barcoding to reduce sequencing errors (see, e.g., Kinde et al., 2011 *Proceedings of the National Academy of Sciences* 108:9530-9535) can be used, as is achieved through the experimental and bioinformatics components of WALDO (see Materials and Methods).

[1142] To determine whether somatic mutation detection was feasible, ten urothelial carcinomas of the upper urinary tract (UTUCs) and normal tissues from the same patients were evaluated. These samples had previously been analyzed by exomic sequencing (Hoang et al., 2013 *Science translational medicine* 5:197ra102-197ra102). For each tumor sample, the number of somatic mutations were counted and the spectrum of single base substitutions (SBS) (A->T, A->C, etc.). It was found that the number of SBS in LINEs was highly correlated with the number of SBS in the exomes of these tumors (R^2=0.98, p <2.6*10^{-8}). The spectrum of mutations in the LINEs was similarly correlated with the spectrum of mutations in exonic sequences (R^2=0.95, p < 1.8*10^{-6}). Noticeably, six of these tumors were from patients exposed to aristolochic acid and the pathognomonic signature (A->T, T->A) of this mutagen was prominent in these six tumors (see Fig. 42, Fig. 43, and Fig. 44).

[1143] The LINEs assessed by WALDO harbor 17,488 mononucleotide tracts of >3 nucleotides. Because mononucleotide tracts are particularly sensitive to defects in mismatch repair, it was determined whether WALDO could be used to assess mismatch repair deficiency. For this purpose, the number of indels in the 17,488 LINE mononucleotide tracts were assessed. It was

found the number of indels in six mismatch repair-deficient colorectal cancers averaged 35 and ranged from 10 to 67. Normal tissues from these patients harbored only zero or one indel, and the difference between the cancers and normal tissues was highly significant ($p<7.2*10^{-4}$).

Example 7: Genome-wide quantification of rare mutations by Bottleneck Sequencing

[1144] The accumulation of random somatic mutations in the nuclear and mitochondrial genome over time underlies fundamental theories of carcinogenesis, neurodegeneration, and aging (see, e.g., Stratton et al., 2009 *Nature* 458:719-724; Kennedy et al., 2012 *Mech Ageing Dev* 133:118-126; and Vijg et al., 2014 *Current opinion in genetics & development* 26:141-149). Direct observation of these rare mutations in the human body with age therefore has the potential to enhance our understanding of human disease. Currently, no *simple* high-throughput method exists to directly and systematically quantify somatic mutational load in normal, non-diseased human tissues at a genome-wide level. Next-generation DNA sequencing (NGS) technologies address this issue, but their sequencing error rate limits the detection of rare mutations (see, e.g., Albertini et al., 1990 *Annu Rev Genet* 24:305-326; and Cole et al., 1994 *Mutat Res* 304:33-105).

[1145] This Example describes a *Bot*tleneck *Seq*uencing *S*ystem (BotSeqS) technology designed to accurately detect rare point mutations in any molecularly-barcoded library in a completely unbiased fashion. BotSeqS, a next-generation sequencing method that simultaneously quantifies rare somatic point mutations across the mitochondrial and nuclear genomes. BotSeqS combines molecular barcoding with a simple dilution step immediately prior to library amplification. In this Example, BotSeqS is used to show age and tissue-dependent accumulations of rare mutations and demonstrate that somatic mutational burden in *normal tissues* can vary by several orders of magnitude, depending on biologic and environmental factors. This Example also shows major differences between the mutational patterns of the mitochondrial and nuclear genomes in normal tissues. Lastly, the mutation spectra of normal tissues were different from each other, but similar to those of the cancers that arose in them. This technology can provide insights into the number and nature of genetic alterations in normal tissues and can be used to address a variety of fundamental questions about the genomes of diseased tissues.

Materials and Methods

Human tissue samples

[1146] Normal, non-diseased tissues for this study were acquired from five different sources (Table 43). For COL229 to COL237 and SIN230, colon or duodenum was obtained from consented patients at the Johns Hopkins Hospital with the approval of its Institutional Review Board. For COL373 to COL375 and BRA01 to BRA09, flash frozen, post-mortem colon and brain was requested from the NIH NeuroBioBank (neurobiobank.nih.gov), with the request being approved and fulfilled by University of Maryland Brain and Tissue Bank (Baltimore, Maryland) and University of Miami Brain Endowment Bank (Miami, Florida). For KID034 to KID038, flash frozen, post-mortem kidney cortex blocks (200 mg) were purchased from Windber Research Institute (Windber, Pennsylvania). COL238 and COL239 were as reported elsewhere (see, e.g., Parsons et al., 1995 *Science* 268:738-740; Hamilton et al., 1995 *The New England journal of medicine* 332:839-847; and De Vos et al., 2004 *American journal of human genetics* 74:954-964). SA_117, SA_118, SA_119, AA_105, AA_124, and AA_126 were as reported elsewhere (see, e.g., Hoang et al., 2013 *Science translational medicine* 5:197ra102). The initial rationale for the sample size for colon and brain was to acquire at least three individuals in each age group in order to understand the average trend of somatic mutational patterns for each age group. Age groups for colon and brain were selected based on human body growth and maintenance: early body development at < 10 years, fully grown young adult body at ~20-40 years, and old, maintained adult body at > 90 years. For colon, one tissue from the young child age group (SIN230) was later determined to be duodenum, leaving only two individuals representing the young child age group for colon epithelium. For normal kidney, criteria for kidney acquisition were an age-matched and non-smoking control group for the kidneys of smokers and aristolochic acid-exposed samples. All normal kidney controls were Caucasian and therefore less likely to originate from a high risk AA-exposed population (e.g. Asia). From the same kidney tissue source, three aliquots of flash frozen, post-mortem normal kidney from a five month old individual were available as technical replicates and to further test an age-trend for non-carcinogen exposed normal kidneys.

Preparation of Illumina Y-adapter-ligated molecules

[1147] Genomic DNA (34 ng to 1 μg) in 55 μL TE buffer was fragmented using BioRuptor (Diagenode) at high intensity for 15 s on and 90 s off, using 7 cycles at 3°C. After random fragmentation, Illumina Y-adapters were ligated to the DNA fragments using TruSeq DNA PCR-Free kit (Illumina) according to a standard low DNA input Illumina protocol with selection for 350 bp insert sizes. This resulted in adapter-ligated molecules in a total volume of 20 μL.

Dilution of Y-adapter-ligated molecules

[1148] Five ten-fold serial dilutions were performed in 96-well PCR plates starting with 2 μL of adapter-ligated molecules (prior to PCR) in 18 μL of dilution buffer (TE containing 1 ng/μL pBlueScript). Samples were mixed by gently pipetting with a multichannel pipette. Two μL of each sample was then transferred into 18 μL of fresh dilution buffer using a multichannel pipette. The mixing and transferring was repeated for a total of five serial dilutions. Only 2 μL of each dilution (1/10 total volume) was used as template for each PCR. A 10^3-fold dilution was accomplished as follows: (i) use of 2 μL of the total 20 μL of adapter-ligated molecules (10-fold dilution); (ii) mixing 2 μL of adapter-ligated molecules with dilution buffer in a total volume of 20 μL (10-fold dilution); and (iii) use of 2 μL of diluted adapter-ligated molecules from the total 20 μL volume in the PCR reaction (10-fold dilution, see below). The five serial dilutions resulted in final dilution factors of 10^3, 10^4, 10^5, 10^6, and 10^7.

PCR amplification of diluted Y-adapter-ligated molecules

[1149] Custom HPLC-purified PCR primers (IDT), TS-PCR Oligo1 (5'-AATGATACGGCGACCACCGAG*A; SEQ ID NO:808) and TS-PCR Oligo2 (5'-CAAGCAGAAGACGGCATACGA*G; SEQ ID NO:809), were designed with one phosphorothioated bond (*) at the 3' end. PCR was performed in 50 μL total volume with 0.5 μM TS-PCR Oligo1, 0.5 μM TS-PCR Oligo2, Q5 2X HotStart High-Fidelity Master Mix (NEB)

at 1X final concentration, and 2 μL of diluted adapter-ligated molecules as template. PCR was performed in Thermo HyBaid PCR Express HBPX Thermal Cycler. The following PCR program was used: 1) 98°C for 30 s 2) 98°C for 10 s, 69°C for 30 s, 72°C for 30 s for 18 cycles, and 3) 72° for 2 min. PCR reactions were purified with AMPure XP (Agilent) at 1.0X bead-to-sample ratio according to the manufacturer's protocol.

MiSeq run and analysis

[1150] A subset of amplified BotSeqS sequencing libraries was evaluated on an Illumina MiSeq instrument (~5 M clusters passed filter per library) to empirically deduce the optimal dilution. The "optimal dilution" was determined to result in 5 to 10 PCR duplicates per molecule when scaled to 1/2 lane of a HiSeq instrument (~70 M clusters passed filter per library in Rapid Run mode). For example, for an input of 500 ng gDNA into the TruSeq PCR-free library prep (selecting for 350 bp insert size), amplified libraries from the 10^4-, 10^5-, 10^6-fold dilutions were sequenced at 2 x 50 bp depth on MiSeq. Three different well-barcoded samples (which were also molecularly barcoded) were multiplexed in one MiSeq lane to test three dilutions of each sample. The .bam output files were uploaded into Galaxy, and Picard's Estimate Library Complexity Tool (Galaxy Tool Version 1.56.0) was executed using the default parameters. Optimal dilutions showed distributions ranging from one to four members per family with singletons comprising ~60-80% of total counts. In general, with an input of 500 ng of gDNA into the TruSeq PCR-free library prep, the 10^5-fold dilution yielded ~10 members per family on a subsequent HiSeq run used for BotSeqS. From our sequencing data, we estimate the average number of high quality clusters required to identify one rare mutation in colonic tissues was (1) 30 M in a normal child, (2) 12 M in a normal young adult, and (3) 5.8 M in a normal old adult.

Whole-genome sequencing

[1151] Thirty-two whole-genome sequencing (WGS) libraries were generated from the 34 individuals in this study. In the remaining two individuals without WGS, COL238 and COL239, Sanger sequence was performed to exclude clonal variants in the BotSeqS data. Of the final 20

μL of adapter-ligated molecules used to prepare BotSeqS libraries (prior to dilution), 10 μL was used to amplify a library for whole-genome sequencing using TruSeq PCR Primer Cocktail (Illumina) and TruSeq PCR Master Mix (Illumina) according to TruSeq PCR protocol. PCR reactions were purified with AMPure XP (Agilent) at 1.0X bead-to-sample ratio according to the manufacturer's instructions. The libraries were PE sequenced 2x100 bp on Illumina HiSeq at >30x coverage.

Spike-in sensitivity experiment

[1152] Two DNA mixtures were prepared from the DNA of normal spleen samples PEN93 and PEN95. Whole genome sequence data was available from these two samples (see, e.g., Jiao et al., 2011 *Science* 331:1199-1203) and SNPs in PEN93 that were not present in PEN95 could be identified. Both mixtures contained the same amount of PEN95 DNA, but the low spike-in mix contained only 10% of the PEN93 DNA contained in the high spike-in mix. BotSeqS libraries from these samples were first analyzed using the normal BotSeqS pipeline to minimize clonal and germline mutations. Indeed only a total of two mutations were detected among the two libraries; these two mutations likely represented rare mutations in the PEN95 sample, and suggest a mutation frequency of ~8 x 10^{-7} mutation/bp. Next, the data were processed through the BotSeqS pipeline *without* filtering out mutations that were present in dbSNP (build 130 and 142). Seven PEN93-specific SNPs in the low spike-in and 89 PEN93-specific SNPs in the high spike-in mixtures were identified. After normalizing for the number of sequenced bases, the "mutation frequency" (number of PEN93-specific SNPs/bp) was 2.71 x 10^{-6} for the low spike-in and 2.01 x 10^{-5} for the high spike-in samples. The difference between the low spike-in and the high spike-in was 7.4-fold, within the range expected from the 10-fold dilution given the relatively low number of mutations identified in the low spike-in sample.

Characterization of BotSeqS specificity

[1153] As one measure of specificity, we identified *rare* mutations as usual except that we used mutations that were present in only one strand rather than in both. Specifically, mutations were

present in ≥ 90% of the Watson family members and the reference sequence was present in ≥ 90% of the Crick family members, or vice versa, but satisfied our other criteria for being "rare". False Watson and Crick pairings were then created, where the Watson strand had overlapping but different coordinates than the Crick strand, and vice versa, to determine if they contained the same mutation by chance. BotSeqS works by having low coverage throughout the genome, generated through the bottleneck dilution step, and precluded this analysis in the nuclear DNA. Instead, mtDNA were used because of the multiple copies of mtDNA per cell. The coverage of mtDNA with BotSeqS is much higher than that of nuclear DNA and facilitated the identification of overlapping molecules. 30 BotSeqS control libraries were processed this way and a total of 146 mtDNA mutations were identified present in one strand only. Using this dataset, each sample was then searched for overlapping molecules and identified 27 examples. None of the 27 false Watson and Crick pairs shared the same artifactual mutation.

[1154] Non-random shearing could produce another type of artifact, falsely suggesting that the Watson and Crick strands of a family were actually derived from two different molecules that coincidentally had the same genomic coordinate. To test for such artifacts, Watson and Crick family pairs were identified that contained the variant in the Watson strand and the reference sequence in the Crick strand, or vice versa, but this time included heterozygous germline variants rather than just the rare variants, and in nuclear DNA rather than in mtDNA. There are many more heterozygous variants in nuclear DNA than in mtDNA because the mtDNA is derived only from the oocyte. The discordances of interest could arise as a result of mispairing of a Watson strand with a Crick strand derived from a different template molecule - i.e., non-random shearing. Alternatively, discordances could result from an amplification error in one of the two strands during an early PCR cycle. Using our WGS data, we first identified 8,535,891 nuclear heterozygous variants observed among the 30 DNA samples used for the control BotSeqS libraries (median of 268,180 variants per library with range 121,851 to 529,922, with the same common variants present in many libraries). From the 8,535,891 nuclear heterozygous variants, we identified a total of 3,960,818 families (median of 123,134 families per library with range 65,832 to 222,135) for which both strands could be evaluated. Of these, 3,960,807 families had the concordant sequence at the variant position in both strands; only 11 heterozygous variants were discordant (i.e., the variant was present in ≥ 90% of the Watson family members and the reference sequence was present in ≥ 90% of the Crick family members, or vice versa). The rate

of discordant germline heterozygous variants was thus 2.78×10^{-6} (11 out of 3,960,818) per bp. This rate is compatible with the known error rate of high fidelity DNA polymerases and could easily represent an amplification error that occurred in one of the two strands during the first PCR cycle, so represents an overestimate of shearing artifacts. Furthermore, it is important to note that BotSeqS eliminates such amplification errors by requiring mutations to be observed on both strands. Because BotSeqS requires mutations to be observed on both strands, the actual false positive rate can be estimated to be $\sim(1/3)(2.78 \times 10^{-6})(2.78 \times 10^{-6}) = 2.58 \times 10^{-12}$.

Generation of BotSeqS change and molecule tables

[1155] Sequence alignments and variant calling were performed with the Illumina secondary analysis package (CASAVA 1.8) using ELANDv2 matching to the GRCh37/hg19 human reference genome. High-quality reads were selected for further analysis only if they satisfied all of the following criteria: (i) passed chastity filter, (ii) read mapped in a proper pair, (iii) ≤ 5 mismatches to reference sequence, and (iv) perfect identity to reference sequence within the first and last five bases of each read. Sequencing reads were grouped into families based on identical paired-end endogenous barcodes. The members of a family were further subdivided into the two possible sequencing orientations to determine the number of Watson and Crick-derived family members. Watson and Crick families had identical genomic coordinates with each end sequenced in opposite reads. Quality scores of identical changes within a family were calculated as the average among the family members. The output for each BotSeqS library was two annotated tables of changes and template molecules (i.e., families).

Selection of high quality changes and molecules

[1156] Custom algorithms were written in Microsoft SQL Server Management Studio to query the changes and molecules tables for each BotSeqS library. Selection criteria are detailed in Table 44 – Table 48. In general, selection was based on quality, clonality, and mappability of single base pair substitutions. For example, it is known that one of the major sources of errors facing all short read alignment and variant callers are artifacts that arise when variants map to

repetitive regions in the genome, including low complexity regions and copy number variants (see, e.g., Li et al., 2014 *Bioinformatics* 30:2843-2851). The BotSeqS pipeline eliminates this universal error in a downstream step by filtering out the genomic noise from repetitive DNA and structural variants (detailed in Table 48). Indels were excluded because they are prone to alignment artifacts and are ~10 times less frequent than spontaneous point mutations. High quality single-base substitutions were defined as those with average quality scores (within the family) of ≥ Q30 and with ≥ 2 reads and ≥ 90% mutation fraction in both the Watson and Crick strands. Variants were considered to be clonal if the variant position was present in the WGS data from that sample or observed in > 1 template molecules (i.e., both strands of more than one UID). Any positions present in dbSNP130 or dbSNP142 were also excluded. It was noticed that the dbSNP filtering drastically minimized recurrent sequencing or mapping artifacts and highly mutable regions. For example, homopolymer tracts (≥8 bp) are mutation hotspots that flood the mutation list. It was observed that nearly all were filtered out with dbSNP142. Finally, families that harbored > 1 mutation were excluded as possible mapping artifacts.

Calculation of mutation frequency

[1157] Mutation frequencies were determined for each BotSeqS library (see Table 51) by dividing the total number of rare mutations by the total bp sequenced. The total bp sequenced was defined by number of families x 2 x read length of each family. The average length of the libraries was ~ 500 bp such that the 100 bp paired-end reads were unlikely to overlap. Only templates with perfect identity to the reference sequence in the first and last 5 bp of every read were considered. The reads were further trimmed by excluding cycle 6 and 7 to ensure quality. Therefore, the actual read length was 88 bases (100-7-5 = 88). For the samples from which technical replicate BotSeqS libraries were generated, the average mutation frequency of the technical replicates was considered the mutation frequency for the sample.

Validation of somatic mutations

[1158] All rare mutations from the nuclear and mtDNA genome passed visual inspection of the sequencing reads. For rare nuclear mutations, Sanger sequencing was performed on a representative set (514 out of 876 mutations). Of these, 514 of 514 (100%) were confirmed to be invisible by Sanger sequencing (excluding the COL238 and COL239 samples that did not have a matched WGS). This demonstrated that these mutations were neither present in the germline nor present in a highly clonal fashion. Mutations confirmed to be absent upon Sanger sequencing are indicated in Table 50.

Comparison to cancer genomes

[1159] Nineteen MAF files representing nuclear somatic mutations from 19 TCGA tumor types were downloaded at synapse.org/#!Synapse:syn1729383 (see, e.g., Kandoth et al., 2013 *Nature* 502:333-339). From the TCGA data, only single-base substitutions were considered and somatic mutations from ultra-mutated tumors were excluded. Mitochondrial DNA somatic mutations from colorectal and renal tumors were derived from supplementary file 2 of Ju et al. (2014 *eLife* 3).

Statistics

[1160] For study design, no prior power analysis or randomization was performed because the variance was initially unknown. The goal of the study was to find major, biologically meaningful differences between the cohorts. To find major differences, sample sizes can be small. Even with the small sample size, however, no violations of the assumptions of the tests were detected, including violations about the homogeneity of variances. T-test and ANOVA analyses were performed using GraphPad Prism 5.0f. Fisher's exact test was performed using R version 3.2.2. Principal component analysis was performed in R. All analyzed samples were reported in the manuscript.

Results

Principles underlying BotSeqS

[1161] The principal feature of BotSeqS is the dilution of any type of a sequencing library prior to PCR amplification. This dilution creates a bottleneck and permits an efficient, random sampling of double-stranded template molecules with a minimal amount of sequencing. Rare mutations, which would normally be masked by an abundance of wild-type sequences in conventional libraries, account for much more of the signal at the corresponding genomic position in a bottlenecked library. Dilution also increases the likelihood that both the "Watson" and "Crick" strands of a DNA molecule will be sequenced redundantly, a feature critical for the high accuracy of BotSeqS and the relatively small amount of sequencing required to implement it. The presence of the same rare mutation on both strands can substantially decrease artifacts and increase specificity (see, e.g., Schmitt et al., 2012 *PNAS U S A* 109:14508-14513). Finally, the random nature of dilution allows DNA molecules from both nuclear and mitochondrial genomes to be assessed from one library.

Generation of BotSeqS libraries

[1162] A standard Illumina TruSeq PCR-Free kit was used to generate 44 BotSeqS libraries from the normal tissues of 34 individuals (Table 43). This included nine individuals with one or two technical replicates. In addition, 10 of our 12 cohorts had more than one biological replicate, each containing two to six individuals.

[1163] The preparation of BotSeqS libraries starts with the random shearing of genomic DNA (Fig. 52). This fragments the genomes into variably-sized DNA molecules, each possessing unique end coordinates called endogenous barcodes (see, e.g., Kinde et al., 2011 *PNAS U S* A 108:9530-9535). Following ligation of standard sequencing adapters to the DNA molecules, the library is diluted to reduce the number of molecules in the population. To identify the correct dilution factor, a ten-fold dilution series was assessed on a MiSeq instrument (Fig. 53). After dilution, PCR amplification of the library generates multiple copies (duplicates) of each DNA

molecule. The endogenous barcodes enables the grouping of sequencing reads into families, also known as UIDs, for *u*nique *id*entifiers (see, e.g., Kinde et al., 2011 *PNAS U S* A 108:9530-9535); each family represents the PCR-derived progeny of a single-stranded template and each member of a family represents the sequence from a single cluster on the Illumina instrument. In the following, we consider the Watson strand to be the sequence derived from the first read of the sequencing instrument (Illumina adapter P5) and the Crick strand to be the sequence derived from the second read (Illumina adapter P7) of each member of the family (Fig. 52). To be considered a potential mutation, BotSeqS required that the identical sequence change be observed in $\geq$ 90% of the Watson and in $\geq$ 90% of the Crick family members and that each family be composed of at least two members. BotSeqS libraries were analyzed using an Illumina HiSeq 2500 instrument on rapid run mode with paired-end reads of 100 bases each. A median of 70 million (M) clusters per library passed the standard Illumina quality filters (range 37 to 188 M clusters per library; Table 43).

BotSeqS data processing pipeline

[1164] The goal of the BotSeqS pipeline was to accurately identify rare, somatic point mutations and to calculate the frequency of these mutations in the sample. To process the data for this purpose, raw sequencing data were input into Illumina's secondary analysis package (CASAVA 1.8) with ELANDv2 mapping to GRCh37/hg19 human reference genome. The BotSeqS pipeline begins by selecting high quality reads for analysis (see Materials and Methods). The data are then organized into two tables for each BotSeqS library: (i) a "change" table listing all differences from the reference sequence and (ii) a unique molecule table listing all families. Importantly, each table contains strand information; almost half (median 45%, range 8% to 62%) of the unique molecules from each BotSeqS library had both the Watson and Crick strands represented in the dataset, ensuring specificity in the subsequent mutation analysis. Moreover, most BotSeqS libraries (37 of 44) had a median number of family members between 5 and 20 (Fig. 56), further demonstrating that the libraries underwent successful bottlenecking.

[1165] To identify rare, somatic mutations, it was necessary to eliminate germline and clonal variants from the BotSeqS data (we defined clonal as those present in both strands of more than one template molecule). We performed whole genome sequencing (WGS) of the same DNA

sample or the same libraries that had been diluted for BotSeqS for 32 of the 34 individuals in this study (Table 43). For the remaining two individuals (COL238 and COL239), Sanger sequencing was performed to eliminate clonal variants, demonstrating that WGS was not necessary for BotSeqS. The vast majority (median 92%, range 88-94%) of variants were found to be germline, easily identifiable from the matched WGS dataset. In addition to clonality, we eliminated potential artifacts by considering only well-mapped positions and by using other filters (Table 44 – Table 48 and Materials and Methods). The requirement for mutations to be present on both strands was indeed necessary because, in the absence of this filter, there was a large number of G>T transversions (Fig. 57), known to represent artifacts in NGS library preparations (see, e.g., Costello et al., 2013 *Nucleic acids research* 41:e67). A "spike-in" validation experiment was further performed by mixing one individual's normal DNA (PEN93) into another individual's normal DNA (PEN95) at two different ratios. Using BotSeqS, it was possible to detect PEN93-specific SNPs in both samples with a 7.4-fold difference in frequency between the low and high spike-ins, within the expected error of the intended 10-fold difference (see Materials and Methods).

[1166] From the 44 BotSeqS libraries, a total of 666 and 876 rare somatic point mutations were identified in mtDNA and nuclear DNA, respectively (Table 49 and Table 50). All rare mutations passed visual inspection and a subset was Sanger-sequenced to confirm that the mutations were not germline or highly prevalent in the samples evaluated (see Materials and Methods). As expected from previous studies, point mutation frequencies of mtDNA ($1.40 \pm 1.29 \times 10^{-5}$ mutation/bp, mean ± s.d.) were significantly higher than those of nuclear DNA ($5.23 \pm 3.47 \times 10^{-7}$) in 25 control individuals (two-tailed t-test, $P < 0.0001$; Table 51). The specificity of BotSeqS was further determined using discordant germline heterozygous calls to estimate a false positive rate of 2.58×10^{-12} (see Materials and Methods).

Mutation frequencies vary with DNA repair capacity and carcinogen exposure

[1167] It was first asked if BotSeqS can detect the elevated levels of mutations in the normal tissues of mismatch repair deficient individuals. Individuals with biallelic inactivating germline mutations in mismatch repair machinery show higher levels of mutation in both normal and tumor tissues (see, e.g., Parsons et al., 1995 *Science* 268:738-740; and Shlien et al., 2015 *Nature*

genetics 47:257-262). Therefore, DNA was tested from normal colon epithelium of individuals (COL238 and COL239) with biallelic germline inactivating mutations in the *Post-Meiotic Segregation 2* (*PMS2*) gene. Using BotSeqS, it was found that the average mutation frequency of nuclear DNA in these two siblings ($6.63 \pm 3.47 \times 10^{-5}$ mutations/bp; ages 16 and 18) was significantly higher than that in similarly aged individuals ($5.13 \pm 1.73 \times 10^{-7}$ for COL235, COL236, COL237, COL374; average age 24) with proficient mismatch repair (two-tailed t-test, $P < 0.05$, Fig. 53a). This 129-fold increase in nuclear mutation frequency was associated with a significant difference in the nuclear mutational spectrum between $PMS2^{+/+}$ and $PMS2^{-/-}$ cohorts (Fisher's exact test, $P = 0.04$, Fig. 53b).

[1168] It was also tested if BotSeqS could identify a high number of mutations in the normal tissues of individuals exposed to environmental carcinogens. Genome-wide sequencing of upper tract urothelial carcinomas was previously performed, representing a cancer type associated with exposure to aristolochic acid (AA) or smoking (see, e.g., Hoang et al., 2013 *Science translational medicine* 5:197ra102). Mutagens in tobacco smoke as well as AA are metabolized to form DNA-adducts in the normal kidney cortrex (see, e.g., Hoang et al., 2013 *Science translational medicine* 5:197ra102; and Randerath et al., 1989 *Journal of the National Cancer Institute* 81:341-347). Four age-matched normal kidney cortices from individuals (KID034, KID035, KID036, KID037; average age 64 years) without known exposure to tobacco smoke or to AA were compared with the normal kidney cortex of three heavy smokers (SA_117, SA_118, SA_119; average age 65 years) as well as with three individuals who had been exposed to AA (AA_105, AA_124, AA_126; average age 79 years). The nuclear point mutation frequencies in smokers and AA-exposed kidneys were significantly higher, by 27- and 36-fold, respectively, than in the non-exposed controls (one-way ANOVA with Bonferroni multiple comparison post-test, $P < 0.0001$ for AA and $P < 0.001$ for smoking) (Fig. 53a). This increased number of mutations in the nuclear genome was associated with a significantly altered nuclear mutational spectrum (Fisher's exact test with Bonferroni multiple comparison correction, $P = 2.58 \times 10^{-8}$ for AA and $P = 1.51 \times 10^{-15}$ for smoking) (Fig. 53b). Interestingly, the mtDNA point mutation frequencies and spectra between the non-exposed and exposed groups were not significantly different, despite the dramatic difference in their nuclear genomes (Fig. 53a, b).

Rare mutations accumulate with age

[1169] Many lines of evidence indicate that the human body accumulates random mutations with age. BotSeqS was designed to *directly* measure differences such as these and we tested whether rare point mutation frequencies in the DNA of three normal human tissues were dependent upon age. Normal colonic epithelium from 11 individuals showed mutation frequencies that significantly increased with age, by an average of 30-fold in mtDNA and 6.1-fold in nuclear DNA, over 91 years (see below and Fig. 54**;** one-way ANOVA with Bonferroni multiple comparison post-test, $P < 0.001$ for both). Similarly, mutation frequencies increased by an average of 19-fold in mtDNA and 6.5-fold in nuclear DNA over 64 years in normal kidney cortices. The mutation frequencies in brain frontal cortex also significantly increased with age, albeit more slowly, by 7.3-fold in mtDNA and 5.7-fold in nuclear DNA over 90 years (one-way ANOVA with Bonferroni multiple comparison post-test, $P < 0.001$ for mtDNA and $P < 0.05$ for nuclear).

Summary of rare mutation frequencies in normal human tissues

Genome	Normal Tissue	Number of Individuals	Mutation Frequency (x10^{-7} mutations/bp)			Average Lifespan (years)	Lifespan Fold-Difference
			Young Child	Young Adult	Old Adult		
mtDNA	Brain	9	18 ± 7	43 ± 6	131 ± 18	89.5	7.3
	Kidney	5	15	nd	277 ± 64	63.8	18.5
	Colon	11	12 ± 17	112 ± 43	365 ± 103	90.8	30.4
Nuclear	Brain	9	1.1 ± 0.3	2.2 ± 1.1	6.3 ± 2.3	89.5	5.7
	Kidney	5	1.2	nd	7.8 ± 1.5	63.8	6.5
	Colon	11	1.8 ± 0.5	5.5 ± 1.6	11 ± 1.5	90.8	6.1

nd, not determined

[1170] Within the dataset, point mutation frequencies in brain versus colonic tissues in three different age groups (children < 10 years; adults between 20 and 40 years; and old adults ≥ 90 years) could be directly comparec. Interestingly, the nuclear mutation frequency in colon was not significantly different from that of the brain in children ($1.81 \pm 0.45 \times 10^{-7}$ in colon vs. $1.06 \pm 0.27 \times 10^{-7}$ in brain, two-way ANOVA with Bonferroni multiple comparison post-test, $P > 0.05$).

However, the mutation frequency in the colon was significantly higher than that of the brain in young adults ($5.51 \pm 1.62 \times 10^{-7}$ in colon vs. $2.16 \pm 1.11 \times 10^{-7}$ in brain, two-way ANOVA with Bonferroni multiple comparison post-test, $P < 0.05$) as well as in old adults ($1.10 \pm 0.15 \times 10^{-6}$ in colon vs. $6.29 \pm 2.31 \times 10^{-7}$ in brain, two-way ANOVA with Bonferroni multiple comparison post-test, $P < 0.01$) (Fig. 58). No significant differences were found between the mtDNA mutation frequency of the colon versus that of brain in relatively young individuals (children or young adults). However, the mtDNA mutation frequency in the colon was significantly higher than that of the brain in old individuals ($3.65 \pm 1.03 \times 10^{-5}$ in colon vs. $1.31 \pm 0.18 \times 10^{-5}$ in brain, two-way ANOVA with Bonferroni multiple comparison post-test, $P < 0.0001$) (Fig. 58).

The mutational patterns in mtDNA are very different from those of nuclear DNA

[1171] The spectra of the rare point mutations in each normal tissue studied were examined. Mutations in mtDNA were dominated by transitions (97% in colon, 89% in kidney, and 91% in brain) with a heavy strand bias, as expected from previous studies[12] (Fig. 54 and Table 49). The ratio of transitions to transversions was strikingly different in mtDNA (average of 15.3) compared to nuclear DNA (average of 1.1) in all three tissues.

[1172] To further assess the differences in mutation frequencies between the two genomes, we calculated the ratio between mtDNA-to-nuclear mutation frequencies for each individual (Table 51). Point mutation frequencies in the mtDNA were on average 24.5-fold higher than the nuclear genome in normal tissues (control cohort, Fig. 59). In patients with exposure histories or DNA repair defects, the ratios were significantly smaller due to the concomitantly greater number of nuclear (but not mitochondrial) DNA mutations in such individuals compared to those from the control cohort (one-way ANOVA with Bonferroni multiple comparison post-test, $P < 0.05$) (Fig. 59).

Mutational spectra are tissue-specific

[1173] Though rare mutations in mtDNA are dominated by transitions, there are still tissue-specific mtDNA differences that can be appreciated from the pie charts in Fig. 3. For example,

mitochondrial C:G to T:A transitions were more prominent, and A:T to G:C transitions less prominent, in normal colon (54% and 42%, respectively) and brain (51% and 40%, respectively) compared to normal kidney tissues (36% and 53%, respectively). The mutation spectra in the nuclear DNA of all three tissues were much more diverse. For example, C:G to T:A transitions predominated in normal colon (44% in colon compared to 22% in kidney and 29% in brain), while normal kidney and brain harbored a proportionately greater fraction of A:T to G:C transitions (25% in kidney and 19% in brain compared to 15% in colon) as well as A:T to C:G transversions (12% in kidney and 16% in brain compared to 5% in colon). Moreover, A:T to T:A transversions were more frequent in kidney (16%) compared to colon (6%) and brain (6%). Pairwise comparisons of the mutational spectra within each genome revealed significant differences between the substitution pattern of kidney and colon (Fisher's exact test with Bonferroni multiple comparison correction, $P = 0.0029$ in mtDNA and $P = 0.0312$ in nuclear DNA).

[1174] The spectra of the rare mutations found in normal kidney and colon tissues were compared to the *clonal* DNA mutations in cancers derived from the cells of these organs, using publically available data for the latter (see, e.g., Ju et al., 2014 *eLife* 3; and Kandoth et al., 2013 *Nature* 502:333-339). Brain frontal cortex was excluded in this analysis because it was not clear what tumor type should be used for comparison. To search for similarities and differences among normal and tumor mutational spectra, principal component analysis was performed on the nuclear and mtDNA spectra derived from the data on normal kidney cortex, normal colon epithelium, clear cell renal carcinoma, and colorectal carcinoma. It was found that the spectra of the rare mutations in normal colon and kidney tissues were very similar to those of the corresponding cancer type (Fig. 60).

Example 8: Safe sequencing system

[1175] Genetic mutations underlie many aspects of life and death including, for example, evolution and disease, respectively (see, e.g., Luria et al., 1943 *Genetics* 28:491-511; Roach et al., 2010 *Science* 328:636-639; Durbin et al., 2010 *Nature* 467:1061-1073; Shibata, 2011 *Carcinogenesis* 32:123-128; McMahon et al., 2007 *N Engl J Med* 356:2614-2621; Eastman et al., 1998 *J Infect Dis* 177:557-564; Chiu et al., 2008 *Proc Natl Acad Sci U S A* 105:20458-

20463; and Fan et al., 2008 *Proc Natl Acad Sci U S A* 105:16266-16271). Detection of such mutations, particularly at a stage prior to their becoming dominant in the population, will likely be essential to optimize diagnoses and/or therapy. For example, in neoplastic diseases, which are all driven by somatic mutations, the applications of rare mutant detection are manifold; they can be used to help identify residual disease at surgical margins or in lymph nodes, to follow the course of therapy when assessed in plasma, and perhaps to identify patients with early, surgically curable disease when evaluated in stool, sputum, plasma, and other bodily fluids (see, e.g., Hoque et al., 2003 *Cancer Res* 63:5723-5726; Thunnissen et al., 2003 *J Clin Pathol* 56:805-810; and Diehl et al., 2008 *Gastroenterology* 135:489-498).

[1176] This Example describes a "Safe-SeqS" (Safe-Sequencing System) to achieve a very high level of accuracy and sensitivity from sequence data. Safe-SeqS can be used to assess the fidelity of a polymerase, the accuracy of in vitro synthesized nucleic acid synthesis, and the prevalence of mutations in nuclear or mitochondrial nucleic acids of normal cells. Safe-SeqS can also be used to detect and/or quantify mosaicsm and somatic mutations. See, also, WO 2012/142213, incorporated herein by reference in its entirety.

Materials and Methods

Endogenous UIDs

[1177] Genomic DNA from human pancreas or cultured lymphoblastoid cells was prepared using Qiagen kits. The pancreas DNA was used for the capture experiment and the lymphoblastoid cells were used for the inverse PCR experiment. DNA was quantified by optical absorbance and with qPCR. DNA was fragmented to an average size of ~200 bp by acoustic shearing (Covaris), then end-repaired, A-tailed, and ligated to Y-shaped adapters according to standard Illumina protocols. The ends of each template molecule provide endogenous UIDs corresponding to their chromosomal positions. After PCR-mediated amplification of the libraries with primer sequences within the adapters, DNA was captured with a filter containing 2,594 nt corresponding to six cancer genes. After capture, 18 cycles of PCR were performed to ensure sufficient amounts of template for sequencing on an Illumina GA IIx instrument.

[1178] For the inverse PCR experiments (Fig. 65), we ligated custom adapters (IDT, Table 57) instead of standard Y-shaped Illumina adapters to sheared cellular DNA. These adapters retained the region complementary to the universal sequencing primer but lacked the grafting sequences required for hybridization to the Illumina GA IIx flow cell. The ligated DNA was diluted into 96 wells and the DNA in each column of 8 wells was amplified with a unique forward primer containing one of 12 index sequences at its 5' end plus a standard reverse primer (Table 57). Amplifications were performed using Phusion HotStart I (NEB) in 50 uL reactions containing 1X Phusion HF buffer, 0.5 mM dNTPs, 0.5 uM each forward and reverse primer (both 5'-phosphorylated), and 1U of Phusion polymerase. The following cycling conditions were used: one cycle of 98˚C for 30s; and 16 cycles of 98˚C for 10s, 65˚C for 30s, and 72˚C for 30s. All 96 reactions were pooled and then purified using a Qiagen MinElute PCR Purification Kit (cat. no. 28004) and a QIAquick Gel Extraction kit (cat. no. 28704). To prepare the circular templates necessary for inverse PCR, DNA was diluted to ~1 ng/uL and ligated with T4 DNA Ligase (Enzymatics) for 30 minutes at room temperature in a 600uL reaction containing 1X T4 DNA Ligation Buffer and 18,000U of T4 DNA Ligase. The ligation reaction was purified using a Qiagen MinElute kit. Inverse PCR was performed using Phusion Hot Start I on 90 ng of circular template distributed in twelve 50 uL reactions, each containing 1X Phusion HF Buffer, 0.25mM dNTPs, 0.5uM each of *KRAS* forward and reverse primers (Table 57) and 1U of Phusion polymerase. The *KRAS*-specific primers both contained grafting sequences for hybridization to the Illumina GA IIx flow cell (Table 57). The following cycling conditions were used: one cycle of 98˚C for 2 minutes; and 37 cycles of 98˚C for 10 seconds, 61˚C for 15 seconds, and 72˚C for 10 seconds. The final purification was performed with a NucleoSpin Extract II kit (Macherey-Nagel) and eluted in 20uL NE Buffer. The resulting DNA fragments contained UIDs composed of three sequences: two endogenous ones, represented by the two ends of the original sheared fragments plus the exogenous sequence introduced during the indexing amplification. As 12 exogenous sequences were used, this increased the number of distinct UIDs by 12-fold over that obtained without exogenous UIDs. This number could easily be increased by using a greater number of distinct primers.

Exogenous UIDs

[1179] Genomic DNA from normal human colonic mucosae or blood lymphocytes was prepared using Qiagen kits. The DNA from colonic mucosae was used for the experiments on *CTNNB1* and mitochondrial DNA, while the lymphocyte DNA was used for the experiments on *CTNNB1* and on polymerase fidelity. DNA was quantified with Digital PCR using primers that amplified single-copy genes from human cells (Analysis of Polymerase Fidelity and *CTNNB1*), qPCR (mitochondrial DNA), or by optical absorbance (oligonucleotides). Each strand of each template molecule was encoded with a 12 or 14 base UID using two cycles of amplicon-specific PCR, as described in the text and Fig. 63. The amplicon-specific primers both contained universal tag sequences at their 5' ends for a later amplification step. The UIDs constituted 12 or 14 random nucleotide sequences appended to the 5' end of the forward amplicon-specific primers (Table 57). These primers can generate 16.8 and 268 million distinct UIDs, respectively. It is important that the number of distinct UIDs greatly exceed the number of original template molecules to minimize the probability that two different original templates acquired the same UID. The UID assignment PCR cycles included Phusion Hot Start II (NEB) in a 45 uL reaction containing 1X Phusion HF buffer, 0.25mM dNTPs, 0.5 uM each forward (containing 12-14 Ns) and reverse primers, and 2U of Phusion polymerase. To keep the final template concentrations <1.5 ng/uL, multiple wells were used to create some libraries. The following cycling conditions were employed: one incubation of 98˚C for 30 seconds (to activate the Phusion Hot Start II); and two cycles of 98˚C for 10 seconds, 61˚C for 120 seconds, and 72˚C for 10 seconds. To ensure complete removal of the first round primers, each well was digested with 60 U of a single strand DNA specific nuclease (Exonuclease-I; Enzymatics) at 37˚C for 1 hour. After a 5 minute heat-inactivation at 98˚C, primers complementary to the introduced universal tags (Table 57) were added to a final concentration of 0.5uM each. These primers contained two terminal phosphorothioates to make them resistant to any residual Exonuclease-I activity. They also contained 5' grafting sequences necessary for hybridization to the Illumina GA IIx flow cell. Finally, they contained an index sequence between the grafting sequence and the universal tag sequence. This index sequence enables the PCR products from multiple different individuals to be simultaneously analyzed in the same flow cell compartment of the sequencer. The following cycling conditions were used for the subsequent 25 cycles of PCR: 98˚C for 10 seconds and 72˚C

for 15 seconds. No intermediate purification steps were performed in an effort to reduce the losses of template molecules.

[1180] After the second round of amplification, wells were consolidated and purified using a Qiagen QIAquick PCR Purification Kit (cat. no. 28104) and eluted in 50 uL EB Buffer (Qiagen). Fragments of the expected size were purified after agarose (mtDNA libraries) or polyacrylamide (all other libraries) gel electrophoresis. For agarose gel purification, the eight 6-uL aliquots were loaded into wells of a 2% Size Select Gel (Invitrogen) and bands of the expected size were collected in EB Buffer as specified by the manufacturer. For polyacrylamide gel purification, ten 5-uL aliquots were loaded into wells of a 10% TBE Polyacrylamide Gel (Invitrogen). Gel slices containing the fragments of interest were excised, crushed, and eluted as described elsewhere (see, e.g., Durbin et al., 2010 *Nature* 467:1061-1073).

Analysis of Phusion polymerase fidelity

[1181] Amplification of a fragment of human genomic DNA within the BMX (RefSeq Accession NM_203281.2) gene was first performed using the PCR conditions described above. The template was diluted so that an average of one template molecule was present in every 10 wells of a 96-well PCR plate. Fifty uL PCR reactions were then performed in 1X Phusion HF buffer, 0.25mM dNTPs, 0.5uM each forward and reverse primers (Table 57), and 2U of Phusion polymerase. The cycling conditions were one cycle of 98˚C for 30 seconds; and 19 cycles of 98˚C for 10 seconds, 61˚C for 120 seconds, and 72˚C for 10 seconds. The primers were removed by digestion with 60 U of Exonuclease-I at 37˚C for 1 hour followed by a 5 minute heat-inactivation at 98˚C. No purification of the PCR product was performed, either before or after Exonuclease-I digestion. The entire contents of each well were then used as templates for the exogenous UIDs strategy described above.

Sequencing

[1182] Sequencing of all the libraries described above was performed using an Illumina GA IIx instrument as specified by the manufacturer. The total length of the reads used for each experiment varied from 36 to 73 bases. Base-calling and sequence alignment was performed with

the Eland pipeline (Illumina). Only high quality reads meeting the following criteria were used for subsequent analysis: (i) the first 25 bases passed the standard Illumina chastity filter; (ii) every base in the read had a quality score ≥20; and (iii) ≤ 3 mismatches to expected sequences. For the exogenous UID libraries, we additionally required the UIDs to have a quality score ≥30. A relatively high frequency of errors was noticed at the ends of the reads in the endogenous UID libraries prepared with the standard Illumina protocol, presumably introduced during shearing or end-repair, so the first and last three bases of these tags were excluded from analysis.

Safe-SeqS analysis

[1183] High quality reads were grouped into UID-families based on their endogenous or exogenous UIDs. Only UID-families with two or more members were considered. Such UID-families included the vast majority (≥99%) of the sequencing reads. To ensure that the same data was used for both conventional and Safe-SeqS analysis, UID-families containing only one member were also excluded from conventional analysis. Furthermore, a base was only identified as "mutant" in conventional sequencing analysis if the same variant was identified in at least two members of at least one UID-family (i.e., two mutations) when comparing conventional analysis to that of Safe-SeqS with exogenous UIDs. For comparison with Safe-SeqS with endogenous UIDs, we required at least two members of each of two UID-families (i.e., four mutations) to identify a position as "mutant" in conventional analysis. With either endogenous or exogenous UIDs, a super-mutant was defined as a UID-family in which ≥95% of members shared the identical mutation. Thus, UID-families with <20 members had to be 100% identical at the mutant position, while a 5% combined replication and sequencing error rate was permitted in UID-families with more members. To determine polymerase fidelity using Safe-SeqS, and to compare the results with previous analyses of Phusion polymerase fidelity, it was necessary to realize that the previous analyses would only detect mutations present in both strands of the PCR products (see, e.g., Shibata, 2011 *Carcinogenesis* 32:123-128). This would be equivalent to analyzing PCR products generated with one less cycle with Safe-SeqS, and the appropriate correction was made in Table 53A. Unless otherwise specified, all values listed in the text and Tables represent means and standard deviations.

Results

Endogenous UIDs

[1184] UIDs, sometimes called barcodes or indexes, can be assigned to nucleic acid fragments in many ways. These include the introduction of exogenous sequences through PCR or ligation. Even more simply, randomly sheared genomic DNA inherently contains UIDs consisting of the sequences of the two ends of each sheared fragment (Fig. 62 and Fig. 65). Paired-end sequencing of these fragments yields UID-families that can be analyzed as described above. To employ such endogenous UIDs in Safe-SeqS, two separate approaches were used: one designed to evaluate many genes simultaneously and the other designed to evaluate a single gene fragment in depth (Fig. 62 and Fig. 65, respectively).

[1185] For the evaluation of multiple genes, standard Illumina sequencing adapters were ligated to the ends of sheared DNA fragments to produce a standard sequencing library, then captured genes of interest on a solid phase. In this experiment, a library made from the DNA of ~15,000 normal cells was used, and 2,594 bp from six genes were targeted for capture. After excluding known single nucleotide polymorphisms, 25,563 apparent mutations, corresponding to 2.4×10^{-4} ± mutations/bp, were also identified (Table 52). Based on previous analyses of mutation rates in human cells, at least 90% of these apparent mutations were likely to represent mutations introduced during template and library preparation or base-calling errors. Note that the error rate determined here (2.4×10^{-4} mutations/bp) is considerably lower than usually reported in experiments using the Illumina instrument because we used very stringent criteria for base calling.

[1186] With Safe-SeqS analysis of the same data, it was determined that 69,505 original template molecules were assessed in this experiment (*i.e.*, 69,505 UID-families, with an average of 40 members per family, were identified, Table 52). All of the polymorphic variants identified by conventional analysis were also identified by Safe-SeqS. However, only 8 super-mutants were observed among these families, corresponding to 3.5×10^{-6} mutations/bp. Thus Safe-SeqS decreased the presumptive sequencing errors by at least 70-fold.

[1187] Safe-SeqS analysis can also determine which strand of a template is mutated, thus an additional criteria for calling mutations could require that the mutation appears in only one or in both strands of the originally double stranded template. Massively parallel sequencers are able to

obtain sequence information from both ends of a template in two sequential reads. (This type of sequencing experiment is called a "paired end" run on the Illumina platform, but similar experiments can be done on other sequencing platforms where they may be called by another name.) The two strands of a double stranded template can be differentiated by the observed orientation of the sequences and the order in which they appear when sequence information is obtained from both ends. For example, a UID strand pair could consist of the following two groups of sequences when each end of a template is sequenced in sequential reads: 1) A sequence in the sense orientation that begins at position 100 of chromosome 2 in the first read followed by a sequence in the antisense orientation that begins at position 400 of chromosome 2 in the second read; and 2) A sequence in the antisense orientation that begins at position 400 of chromosome 2 in the first read followed by a sequence in the sense orientation that begins at position 100 of chromosome 2 in the second read. In the capture experiment described above, 42,222 of 69,505 UIDs (representing 21,111 original double stranded molecules) in the region of interest represented UID strand pairs. These 42,222 UIDs encompassed 1,417,838 bases in the region of interest. When allowing a mutation to only occur within UID strand pairs (whether in one or both strands), two super-mutants were observed, yielding a mutation rate of 1.4×10^{-6} super-mutants/bp. When requiring that a mutation occur in only one strand of a UID strand pair, only one super-mutant was observed, yielding a mutation rate of 7.1×10^{-7} super-mutants/bp. When requiring that a mutation occur in both strands of a UID strand pair, only one super-mutant was observed, yielding a mutation rate of 7.1×10^{-7} super-mutants/bp. Thus, requiring that mutations occur in only one or in both strands of templates can further increase the specificity of Safe-SeqS.

[1188] A strategy employing endogenous UIDs was also used to reduce false positive mutations upon deep sequencing of a single region of interest. In this case, a library prepared as described above from ~1,750 normal cells was used as template for inverse PCR employing primers complementary to a gene of interest, so the PCR products could be directly used for sequencing (Fig. 65). With conventional analysis, an average of 2.3×10^{-4} mutations/bp were observed, similar to that observed in the capture experiment (Table 52). Given that only 1,057 independent molecules from normal cells were assessed in this experiment, as determined through Safe-SeqS analysis, all mutations observed with conventional analysis likely represented false positives

(Table 52). With Safe-SeqS analysis of the same data, no super-mutants were identified at any position.

Exogenous UIDs

[1189] Though the results described above show that Safe-SeqS can increase the reliability of massively parallel sequencing, the number of different molecules that can be examined using endogenous UIDs is limited. For fragments sheared to an average size of 150 bp (range 125-175), 36 base paired-end sequencing can evaluate a maximum of ~7,200 different molecules containing a specific mutation (2 reads x 2 orientations x 36 bases/read x 50 base variation on either end of the fragment). In practice, the actual number of UIDs is smaller because the shearing process is not entirely random.

[1190] To make more efficient use of the original templates, a Safe-SeqS strategy was developed that employed a minimum number of enzymatic steps. This strategy also permitted the use of degraded or damaged DNA, such as found in clinical specimens or after bisulfite-treatment for the examination of cytosine methylation. As depicted in Fig. 63, this strategy employs two sets of PCR primers. The first set is synthesized with standard phosphoramidite precursors and contained sequences complementary to the gene of interest on the 3' end and different tails at the 5' ends of both the forward and reverse primers. The different tails allowed universal amplification in the next step. Finally, there was a stretch of 12 to 14 random nucleotides between the tail and the sequence-specific nucleotides in the forward primer. The random nucleotides form the UIDs. An equivalent way to assign UIDs to fragments, not used in this study, would employ 10,000 forward primers and 10,000 reverse primers synthesized on a microarray. Each of these 20,000 primers would have gene-specific primers at their 3'-ends and one of 10,000 specific, predetermined, non-overlapping UID sequences at their 5'-ends, allowing for 10^8 (i.e., $[10^4]^2$) possible UID combinations. In either case, two cycles of PCR are performed with the primers and a high-fidelity polymerase, producing a uniquely tagged, double-stranded DNA fragment from each of the two strands of each original template molecule (Fig. 63). The residual, unused UID assignment primers are removed by digestion with a single-strand specific exonuclease, without further purification, and two new primers are added. Alternatively or in addition to such digestion, one can use a silica column that selectively retains larger-sized

fragments or one can use solid phase reversible immobilization (SPRI) beads under conditions that selectively retain larger fragments to eliminate smaller, non-specific, amplification artifacts. This purification may potentially help in reducing primer-dimer accumulation in later steps. The new primers, complementary to the tails introduced in the UID assignment cycles, contain grafting sequences at their 5' ends, permitting solid-phase amplification on the Illumina instrument, and phosphorothioate residues at their 3' ends to make them resistant to any remaining exonuclease. Following 25 additional cycles of PCR, the products are loaded on the Illumina instrument. As shown below, this strategy allowed us to evaluate the majority of input fragments and was used for several illustrative experiments.

Analysis of DNA polymerase fidelity

[1191] Measurement of the error rates of DNA polymerases is essential for their characterization and dictates the situations in which these enzymes can be used. The error rate of Phusion polymerase was measured, as this polymerase has one of the lowest reported error frequencies of any commercially available enzyme and therefore poses a particular challenge for an in vitro-based approach. A single human DNA template molecule, comprising a segment of an arbitrarily chosen human gene, was first amplified through 19 rounds of PCR. The PCR products from these amplifications, in their entirety, were used as templates for Safe-SeqS as described in Fig. 63. In seven independent experiments of this type, the number of UID-families identified by sequencing was 624,678 ± 421,274, which is consistent with an amplification efficiency of 92 ± 9.6% per round of PCR.

[1192] The error rate of Phusion polymerase, estimated through cloning of PCR products encoding β-galactosidase in plasmid vectors and transformation into bacteria, is reported by the manufacturer to be 4.4×10^{-7} errors/bp/PCR cycle. Even with very high stringency base-calling, conventional analysis of the Illumina sequencing data revealed an apparent error rate of 9.1×10^{-6} errors/bp/PCR cycle, more than an order of magnitude higher than the reported Phusion polymerase error rate (Table 53A). In contrast, Safe-SeqS of the same data revealed an error rate of 4.5×10^{-7} errors/bp/PCR cycle, nearly identical to that measured for Phusion polymerase in biological assays (Table 53A). The vast majority (>99%) of these errors were single base substitutions (Table 54A), consistent with previous data on the mutation spectra created by other

prokaryotic DNA polymerases (Tindall et al. 1988 *Biochemistry* 27:6008-6013; de Boer et al., 1988 *Genetics* 118:181-191; Eckert et al., 1990 *Nucleic Acids Res* 18:3739-3744).

[1193] Safe-SeqS also allowed a determination of the total number of distinct mutational events and an estimation of PCR cycle in which the mutation occurred. There were 19 cycles of PCR performed in wells containing a single template molecule in these experiments. If a polymerase error occurred in cycle 19, there would be only one super-mutant produced (from the strand containing the mutation). If the error occurred in cycle 18 there should be two super-mutants (derived from the mutant strands produced in cycle 19), etc. Accordingly, the cycle in which the error occurred is related to the number of super-mutants containing that error. The data from seven independent experiments demonstrate a relatively consistent number of observed total polymerase errors ($2.2 \pm 1.1 \times 10^{-6}$ distinct mutations/bp), in good agreement with the expected number of observations from simulations ($1.5 \pm 0.21 \times 10^{-6}$ distinct mutations/bp). The data also show a highly variable timing of occurrence of polymerase errors among experiments (Table 55). This kind of information is difficult to derive using conventional analysis of the same next-generation sequencing data, in part because of the prohibitively high apparent mutation rate noted above.

Analysis of oligonucleotide composition

[1194] A small number of mistakes during the synthesis of oligonucleotides from phoshoramidite precursors are tolerable for most applications, such as routine PCR or cloning. However, for synthetic biology, wherein many oligonucleotides must be joined together, such mistakes present a major obstacle to success. Clever strategies for making the gene construction process more efficient have been devised (see, e.g., Kosuri et al., 2010 *Nat Biotechnol* 28:1295-129; and Matzas et al., 2010 *Nat Biotechnol* 28:1291-1294), but all such strategies would benefit from more accurate synthesis of the oligonucleotides themselves. Determining the number of errors in synthesized oligonucleotides is difficult because the fraction of oligonucleotides containing errors can be lower than the sensitivity of conventional next-generation sequencing analyses.

[1195] To determine whether Safe-SeqS could be used for this determination, standard phosphoramidite chemistry was used to synthesize an oligonucleotide containing 31 bases that

were designed to be identical to that analyzed in the polymerase fidelity experiment described above. In the synthetic oligonucleotide, the 31 bases were surrounded by sequences complementary to primers that could be used for the UID assignment steps of Safe-SeqS (Fig. 63). By performing Safe-SeqS on ~300,000 oligonucleotides, it was found that there were 8.9 ± 0.28 x 10^{-4} super-mutants/bp and that these errors occurred throughout the oligonucleotides (Fig. 66A). The oligonucleotides contained a large number of insertion and deletion errors, representing 8.2 ± 0.63% and 25 ± 1.5% of the total super-mutants, respectively. Importantly, both the position and nature of the errors were highly reproducible among seven independent replicates of this experiment performed on the same batch of oligonucleotides (Fig. 66A). This nature and distribution of errors had little in common with that of the errors produced by Phusion polymerase (Fig. 66B and Table 56), which were distributed in the expected stochastic pattern among replicate experiments. The number of errors in the oligonucleotides synthesized with phosphoramidites was ~60 times higher than in the equivalent products synthesized by Phusion polymerase. These data, *in toto*, indicate that the vast majority of errors in the former were generated during their synthesis rather than during the Safe-SeqS procedure.

[1196] Does Safe-SeqS preserve the ratio of mutant:normal sequences in the original templates? To address this question, two 31-base oligonucleotides of identical sequence with the exception of nt 15 (50:50 C/G instead of T) were synthesized and mixed them at nominal mutant/normal fractions of 3.3% and 0.33%. Through Safe-SeqS analysis of the oligonucleotide mixtures, it was found that the ratios were 2.8% and 0.27%, respectively. Thus, the UID assignment and amplification procedures used in Safe-SeqS do not greatly alter the proportion of variant sequences and thereby provide a reliable estimate of that proportion when unknown. This is also supported by the reproducibility of variant fractions when analyzed in independent Safe-SeqS experiments (Fig. 66A).

Analysis of DNA sequences from normal human cells

[1197] The exogenous UID strategy (Fig. 63) was then used to determine the prevalence of rare mutations in a small region of the *CTNNB1* gene from ~100,000 normal human cells from three unrelated individuals. Through comparison with the number of UID-families obtained in the Safe-SeqS experiments (Table 53B), it was calculated that the majority (78 ± 9.8 %) of the input

fragments were converted into UID-families. There was an average of 68 members/UID-family, easily fulfilling the required redundancy for Safe-SeqS (Fig. 67). Conventional analysis of the Illumina sequencing data revealed an average of 118,488 ± 11,357 mutations among the ~560 Mb of sequence analyzed per sample, corresponding to an apparent mutation prevalence of 2.1 ± 0.16 x 10^{-4} mutations/bp (Table 53B). Only an average of 99 ± 78 super-mutants were observed in the Safe-SeqS analysis. The vast majority (>99%) of super-mutants were single base substitutions and the calculated mutation rate was 9.0 ± 3.1 x 10^{-6} mutations/bp (Table 54B). Safe-SeqS thereby reduced the apparent frequency of mutations in genomic DNA by at least 24-fold (Fig. 64).

[1198] One possible strategy to increase the specificity of Safe-SeqS is to perform the library amplification (and possibly the UID assignment cycles) in multiple wells. This can be accomplished in as few as 2 or as many as 384 wells using standard PCR plates, or scaled up to many more wells when using a microfluidic device (thousands to millions). When performed this way, indexing sequences can be introduced into the templates that are unique to the wells in which the template is amplified. Rare mutations, thus, should give rise to two super-mutants (i.e., one from each strand), both with the same well index sequence. When performing Safe-SeqS with exogenous UIDs on the *CTNNB1* templates described above and diluted into 10 wells (each well yielding templates amplified with a different index sequence), the mutation rate was further reduced from 9.0 ± 3.1 x 10^{-6} to 3.7 ± 1.2 x 10^{-6} super-mutants/bp. Thus, analyzing templates in multiple compartments—in a manner that yields differentially encoded templates based on the compartment in which templates were amplified—may be an additional strategy to increase the specificity of Safe-SeqS.

Analysis of DNA sequences from mitochondrial DNA

[1199] The identical strategy was applied to a short segment of mitochondrial DNA in ~1,000 cells from each of seven unrelated individuals. Conventional analysis of the Illumina sequencing libraries produced with the Safe-SeqS procedure (Fig. 63) revealed an average of 30,599 ± 12,970 mutations among the ~150 Mb of sequence analyzed per sample, corresponding to an apparent mutation prevalence of 2.1 ± 0.94 x 10^{-4} mutations/bp (Table 53C). Only 135 ± 61 super-mutants were observed in the Safe-SeqS analysis. As with the *CTNNB1* gene, the vast majority of mutations were single base substitutions, though occasional single base deletions were also observed (Table 54C). The calculated mutation rate in the analyzed segment of

mtDNA was $1.4 \pm 0.68 \times 10^{-5}$ mutations/bp (Table 53C). Thus, Safe-SeqS thereby reduced the apparent frequency of mutations in genomic DNA by at least 15-fold.

Example 9: Detection of Genetic and Protein Biomarkers in Combination with Detection of Aneuploidy

[1200] Samples from a number of patients were tested for the presence of genetic biomarkers (NRAS, CTNNB1, PIK3CA, FBXW7, APC, EGFR, BRAF, CDKN2A, PTEN, FGFR2, HRAS, KRAS, AKT1, TP53, PPP2R1A, and/or GNAS) and protein biomarkers (CA19-9, CEA, HGF, OPN, CA125, prolactin, TIMP-1, and/or MPO). The same samples were also tested for the presence of aneuploidy using WALDO methods described herein. The results are shown in Table 59. As can be seen, the genetic and protein biomarker test can complement the aneuploidy test (e.g., some patients are negative for the genetic and protein biomarker test while being positive for aneuploidy, and vice versa), such that the presence of cancer can be more accurately and completely detected using both tests.

[1201] Once a subject, is identified as having cancer by the genetic and protein biomarker test, the aneuploidy test, or both, the subject can undergo further diagnostic testing and/or increased monitoring (e.g., any of the variety of further diagnostic testing and/or increased monitoring methods described herein) and/or be administered a therapeutic intervention (e.g., any of the variety of therapeutic interventions described herein).
