Localization sequences for gene modifying systems

In certain embodiments, a gene editor system RNA further comprises an intracellular localization sequence, e.g., a nuclear localization sequence (NLS). In some embodiments, a gene modifying polypeptide comprises an NLS as comprised in SEQ ID NO: 4000 and/or SEQ ID NO: 4001, or an NLS having an amino acid sequence having at least 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, or 99% identity thereto.

The nuclear localization sequence may be an RNA sequence that promotes the import of the RNA into the nucleus. In certain embodiments the nuclear localization signal is located on the template RNA. In certain embodiments, the gene modifying polypeptide is encoded on a first RNA, and the template RNA is a second, separate, RNA, and the nuclear localization signal is located on the template RNA and not on an RNA encoding the gene modifying polypeptide. While not wishing to be bound by theory, in some embodiments, the RNA encoding the gene modifying polypeptide is targeted primarily to the cytoplasm to promote its translation, while the template RNA is targeted primarily to the nucleus to promote insertion into the genome. In some embodiments the nuclear localization signal is at the 3′ end, 5′ end, or in an internal region of the template RNA. In some embodiments the nuclear localization signal is 3′ of the heterologous sequence (e.g., is directly 3′ of the heterologous sequence) or is 5′ of the heterologous sequence (e.g., is directly 5′ of the heterologous sequence). In some embodiments the nuclear localization signal is placed outside of the 5′ UTR or outside of the 3′ UTR of the template RNA. In some embodiments the nuclear localization signal is placed between the 5′ UTR and the 3′ UTR, wherein optionally the nuclear localization signal is not transcribed with the transgene (e.g., the nuclear localization signal is an anti-sense orientation or is downstream of a transcriptional termination signal or polyadenylation signal). In some embodiments the nuclear localization sequence is situated inside of an intron. In some embodiments a plurality of the same or different nuclear localization signals are in the RNA, e.g., in the template RNA. In some embodiments the nuclear localization signal is less than 5, 10, 25, 50, 75, 100, 150, 200, 250, 300, 350, 400, 450, 500, 600, 700, 800, 900 or 1000 bp in length. Various RNA nuclear localization sequences can be used. For example, Lubelsky and Ulitsky, *Nature* 555 (107-111), 2018 describe RNA sequences which drive RNA localization into the nucleus. In some embodiments, the nuclear localization signal is a SINE-derived nuclear RNA localization (SIRLOIN) signal. In some

embodiments the nuclear localization signal binds a nuclear-enriched protein. In some embodiments the nuclear localization signal binds the HNRNPK protein. In some embodiments the nuclear localization signal is rich in pyrimidines, e.g., is a C/T rich, C/U rich, C rich, T rich, or U rich region. In some embodiments the nuclear localization signal is derived from a long non-coding RNA. In some embodiments the nuclear localization signal is derived from MALAT1 long non-coding RNA or is the 600 nucleotide M region of MALAT1 (described in Miyagawa et al., *RNA* 18, (738-751), 2012). In some embodiments the nuclear localization signal is derived from BORG long non-coding RNA or is a AGCCC motif (described in Zhang et al., *Molecular and Cellular Biology* 34, 2318-2329 (2014). In some embodiments the nuclear localization sequence is described in Shukla et al., *The EMBO Journal* e98452 (2018). In some embodiments the nuclear localization signal is derived from a retrovirus.

In some embodiments, a polypeptide described herein comprises one or more (e.g., 2, 3, 4, 5) nuclear targeting sequences, for example a nuclear localization sequence (NLS). In some embodiments, the NLS is a bipartite NLS. In some embodiments, an NLS facilitates the import of a protein comprising an NLS into the cell nucleus. In some embodiments, the NLS is fused to the N-terminus of a gene modifying polypeptide as described herein. In some embodiments, the NLS is fused to the C-terminus of the gene modifying polypeptide. In some embodiments, the NLS is fused to the N-terminus or the C-terminus of a Cas domain. In some embodiments, a linker sequence is disposed between the NLS and the neighboring domain of the gene modifying polypeptide.

In some embodiments, an NLS comprises the amino acid sequence MDSLLMNRRKFLYQFKNVRWAKGRRETYLC (SEQ ID NO: 5009), PKKRKVEGADKRTADGSEFESPKKKRKV(SEQ ID NO: 5010), RKSGKIAAIWKRPRKPKKKRKV (SEQ ID NO: 5011) KRTADGSEFESPKKKRKV(SEQ ID NO: 5012), KKTELQTTNAENKTKKL (SEQ ID NO: 5013), or KRGINDRNFWRGENGRKTR (SEQ ID NO: 5014), KRPAATKKAGQAKKKK (SEQ ID NO: 5015), PAAKRVKLD (SEQ ID NO: 4644), KRTADGSEFEKRTADGSEFESPKKKAKVE (SEQ ID NO: 4649), KRTADGSEFE (SEQ ID NO: 4650), KRTADGSEFESPKKKAKVE (SEQ ID NO: 11098), AGKRTADGSEFEKRTADGSEFESPKKKAKVE (SEQ ID NO: 4651), or a functional fragment or variant thereof. Exemplary NLS sequences are also described in

PCT/EP2000/011690, the contents of which are incorporated herein by reference for their disclosure of exemplary nuclear localization sequences. In some embodiments, an NLS comprises an amino acid sequence as disclosed in Table 11. An NLS of this table may be utilized with one or more copies in a polypeptide in one or more locations in a polypeptide, e.g., 1, 2, 3 or more copies of an NLS in an N-terminal domain, between peptide domains, in a C-terminal domain, or in a combination of locations, in order to improve subcellular localization to the nucleus. Multiple unique sequences may be used within a single polypeptide. Sequences may be naturally monopartite or bipartite, e.g., having one or two stretches of basic amino acids, or may be used as chimeric bipartite sequences. Sequence references correspond to UniProt accession numbers, except where indicated as SeqNLS for sequences mined using a subcellular localization prediction algorithm (Lin et al BMC Bioinformat 13:157 (2012), incorporated herein by reference in its entirety).

In some embodiments, the NLS is a bipartite NLS. A bipartite NLS typically comprises two basic amino acid clusters separated by a spacer sequence (which may be, e.g., about 10

amino acids in length). A monopartite NLS typically lacks a spacer. An example of a bipartite NLS is the nucleoplasmin NLS, having the sequence KR[PAATKKAGQA]KKKK (SEQ ID NO: 5015), wherein the spacer is bracketed. Another exemplary bipartite NLS has the sequence PKKKRKVEGADKRTADGSEFESPKKKRKV (SEQ ID NO: 5016). Exemplary NLSs are described in International Application WO2020051561, which is herein incorporated by reference in its entirety, including for its disclosures regarding nuclear localization sequences.

In certain embodiments, a gene editor system polypeptide (e.g., a gene modifying polypeptide as described herein) further comprises an intracellular localization sequence, e.g., a nuclear localization sequence and/or a nucleolar localization sequence. The nuclear localization sequence and/or nucleolar localization sequence may be amino acid sequences that promote the import of the protein into the nucleus and/or nucleolus, where it can promote integration of heterologous sequence into the genome. In certain embodiments, a gene editor system polypeptide (e.g., (e.g., a gene modifying polypeptide as described herein) further comprises a nucleolar localization sequence. In certain embodiments, the gene modifying polypeptide is encoded on a first RNA, and the template RNA is a second, separate, RNA, and the nucleolar localization signal is encoded on the RNA encoding the gene modifying polypeptide and not on the template RNA. In some embodiments, the nucleolar localization signal is located at the N-terminus, C-terminus, or in an internal region of the polypeptide. In some embodiments, a plurality of the same or different nucleolar localization signals are used. In some embodiments, the nuclear localization signal is less than 5, 10, 25, 50, 75, or 100 amino acids in length. Various polypeptide nucleolar localization signals can be used. For example, Yang et al., *Journal of Biomedical Science* 22, 33 (2015), describe a nuclear localization signal that also functions as a nucleolar localization signal. In some embodiments, the nucleolar localization signal may also be a nuclear localization signal. In some embodiments, the nucleolar localization signal may overlap with a nuclear localization signal. In some embodiments, the nucleolar localization signal may comprise a stretch of basic residues. In some embodiments, the nucleolar localization signal may be rich in arginine and lysine residues. In some embodiments, the nucleolar localization signal may be derived from a protein that is enriched in the nucleolus. In some embodiments, the nucleolar localization signal may be derived from a protein enriched at ribosomal RNA loci. In some embodiments, the nucleolar localization signal may be derived from a protein that binds rRNA. In some embodiments, the nucleolar localization signal may be derived from MSP58. In

some embodiments, the nucleolar localization signal may be a monopartite motif. In some embodiments, the nucleolar localization signal may be a bipartite motif. In some embodiments, the nucleolar localization signal may consist of a multiple monopartite or bipartite motifs. In some embodiments, the nucleolar localization signal may consist of a mix of monopartite and bipartite motifs. In some embodiments, the nucleolar localization signal may be a dual bipartite motif. In some embodiments, the nucleolar localization motif may be a KRASSQALGTIPKRRSSSRFIKRKK (SEQ ID NO: 5017). In some embodiments, the nucleolar localization signal may be derived from nuclear factor-κB-inducing kinase. In some embodiments, the nucleolar localization signal may be an RKKRKKK motif (SEQ ID NO: 5018) (described in Birbach et al., Journal of Cell Science, 117 (3615-3624), 2004).

Evolved Variants of Gene Modifying Polypeptides and Systems

In some embodiments, the invention provides evolved variants of gene modifying polypeptides as described herein. Evolved variants can, in some embodiments, be produced by mutagenizing a reference gene modifying polypeptide, or one of the fragments or domains comprised therein. In some embodiments, one or more of the domains (e.g., the reverse transcriptase domain) is evolved. One or more of such evolved variant domains can, in some embodiments, be evolved alone or together with other domains. An evolved variant domain or domains may, in some embodiments, be combined with unevolved cognate component(s) or evolved variants of the cognate component(s), e.g., which may have been evolved in either a parallel or serial manner.

In some embodiments, the process of mutagenizing a reference gene modifying polypeptide, or fragment or domain thereof, comprises mutagenizing the reference gene modifying polypeptide or fragment or domain thereof. In embodiments, the mutagenesis comprises a continuous evolution method (e.g., PACE) or non-continuous evolution method (e.g., PANCE), e.g., as described herein. In some embodiments, the evolved gene modifying polypeptide, or a fragment or domain thereof, comprises one or more amino acid variations introduced into its amino acid sequence relative to the amino acid sequence of the reference gene modifying polypeptide, or fragment or domain thereof. In embodiments, amino acid sequence variations may include one or more mutated residues (e.g., conservative substitutions, non-conservative substitutions, or a combination thereof) within the amino acid sequence of a

reference gene modifying polypeptide, e.g., as a result of a change in the nucleotide sequence encoding the gene modifying polypeptide that results in, e.g., a change in the codon at any particular position in the coding sequence, the deletion of one or more amino acids (e.g., a truncated protein), the insertion of one or more amino acids, or any combination of the foregoing. The evolved variant gene modifying polypeptide may include variants in one or more components or domains of the gene modifying polypeptide (e.g., variants introduced into a reverse transcriptase domain).

In some aspects, the disclosure provides gene modifying polypeptides, systems, kits, and methods using or comprising an evolved variant of a gene modifying polypeptide, e.g., employs an evolved variant of a gene modifying polypeptide or a gene modifying polypeptide produced or producible by PACE or PANCE. In embodiments, the unevolved reference gene modifying polypeptide is a gene modifying polypeptide as disclosed herein.

The term "phage-assisted continuous evolution (PACE),"as used herein, generally refers to continuous evolution that employs phage as viral vectors. Examples of PACE technology have been described, for example, in International PCT Application No. PCT/US 2009/056194, filed September 8, 2009, published as WO 2010/028347 on March 11, 2010; International PCT Application, PCT/US2011/066747, filed December 22, 2011, published as WO 2012/088381 on June 28, 2012; U.S. Patent No. 9,023,594, issued May 5, 2015; U.S. Patent No. 9,771,574, issued September 26, 2017; U.S. Patent No. 9,394,537, issued July 19, 2016; International PCT Application, PCT/US2015/012022, filed January 20, 2015, published as WO 2015/134121 on September 11, 2015; U.S. Patent No. 10,179,911, issued January 15, 2019; and International PCT Application, PCT/US2016/027795, filed April 15, 2016, published as WO 2016/168631 on October 20, 2016, the entire contents of each of which are incorporated herein by reference.

The term "phage-assisted non-continuous evolution (PANCE)," as used herein, generally refers to non-continuous evolution that employs phage as viral vectors. Examples of PANCE technology have been described, for example, in Suzuki T. et al, Crystal structures reveal an elusive functional domain of pyrrolysyl-tRNA synthetase, Nat Chem Biol. 13(12): 1261-1266 (2017), incorporated herein by reference in its entirety. Briefly, PANCE is a technique for rapid *in vivo* directed evolution using serial flask transfers of evolving selection phage (SP), which contain a gene of interest to be evolved, across fresh host cells (e.g., E. coli cells). Genes inside the host cell may be held constant while genes contained in the SP continuously evolve.

Following phage growth, an aliquot of infected cells may be used to transfect a subsequent flask containing host E. coli. This process can be repeated and/or continued until the desired phenotype is evolved, e.g., for as many transfers as desired.

Methods of applying PACE and PANCE to gene modifying polypeptides may be readily appreciated by the skilled artisan by reference to, *inter alia*, the foregoing references. Additional exemplary methods for directing continuous evolution of genome-modifying proteins or systems, e.g., in a population of host cells, e.g., using phage particles, can be applied to generate evolved variants of gene modifying polypeptides, or fragments or subdomains thereof. Non-limiting examples of such methods are described in International PCT Application, PCT/US2009/056194, filed September 8, 2009, published as WO 2010/028347 on March 11, 2010; International PCT Application, PCT/US2011/066747, filed December 22, 2011, published as WO 2012/088381 on June 28, 2012; U.S. Patent No. 9,023,594, issued May 5, 2015; U.S. Patent No. 9,771,574, issued September 26, 2017; U.S. Patent No. 9,394,537, issued July 19, 2016; International PCT Application, PCT/US2015/012022, filed January 20, 2015, published as WO 2015/134121 on September 11, 2015; U.S. Patent No. 10,179,911, issued January 15, 2019; International Application No. PCT/US2019/37216, filed June 14, 2019, International Patent Publication WO 2019/023680, published January 31, 2019, International PCT Application, PCT/US2016/027795, filed April 15, 2016, published as WO 2016/168631 on October 20, 2016, and International Patent Publication No. PCT/US2019/47996, filed August 23, 2019, each of which is incorporated herein by reference in its entirety.

In some non-limiting illustrative embodiments, a method of evolution of a evolved variant gene modifying polypeptide, of a fragment or domain thereof, comprises: (a) contacting a population of host cells with a population of viral vectors comprising the gene of interest (the starting gene modifying polypeptide or fragment or domain thereof), wherein: (1) the host cell is amenable to infection by the viral vector; (2) the host cell expresses viral genes required for the generation of viral particles; (3) the expression of at least one viral gene required for the production of an infectious viral particle is dependent on a function of the gene of interest; and/or (4) the viral vector allows for expression of the protein in the host cell, and can be replicated and packaged into a viral particle by the host cell. In some embodiments, the method comprises (b) contacting the host cells with a mutagen, using host cells with mutations that elevate mutation rate (e.g., either by carrying a mutation plasmid or some genome modification—e.g., proofing-

impaired DNA polymerase, SOS genes, such as UmuC, UmuD', and/or RecA, which mutations, if plasmid-bound, may be under control of an inducible promoter), or a combination thereof. In some embodiments, the method comprises (c) incubating the population of host cells under conditions allowing for viral replication and the production of viral particles, wherein host cells are removed from the host cell population, and fresh, uninfected host cells are introduced into the population of host cells, thus replenishing the population of host cells and creating a flow of host cells. In some embodiments, the cells are incubated under conditions allowing for the gene of interest to acquire a mutation. In some embodiments, the method further comprises (d) isolating a mutated version of the viral vector, encoding an evolved gene product (e.g., an evolved variant gene modifying polypeptide, or fragment or domain thereof), from the population of host cells.

The skilled artisan will appreciate a variety of features employable within the above-described framework. For example, in some embodiments, the viral vector or the phage is a filamentous phage, for example, an M13 phage, e.g., an M13 selection phage. In certain embodiments, the gene required for the production of infectious viral particles is the M13 gene III (gIII). In embodiments, the phage may lack a functional gIII, but otherwise comprise gI, gII, gIV, gV, gVI, gVII, gVIII, gIX, and a gX. In some embodiments, the generation of infectious VSV particles involves the envelope protein VSV-G. Various embodiments can use different retroviral vectors, for example, Murine Leukemia Virus vectors, or Lentiviral vectors. In embodiments, the retroviral vectors can efficiently be packaged with VSV-G envelope protein, e.g., as a substitute for the native envelope protein of the virus.

In some embodiments, host cells are incubated according to a suitable number of viral life cycles, e.g., at least 10, at least 20, at least 30, at least 40, at least 50, at least 100, at least 200, at least 300, at least 400, at least, 500, at least 600, at least 700, at least 800, at least 900, at least 1000, at least 1250, at least 1500, at least 1750, at least 2000, at least 2500, at least 3000, at least 4000, at least 5000, at least 7500, at least 10000, or more consecutive viral life cycles, which in on illustrative and non-limiting examples of M13 phage is 10-20 minutes per virus life cycle. Similarly, conditions can be modulated to adjust the time a host cell remains in a population of host cells, e.g., about 10, about 11, about 12, about 13, about 14, about 15, about 16, about 17, about 18, about 19, about 20, about 21, about 22, about 23, about 24, about 25, about 30, about 35, about 40, about 45, about 50, about 55, about 60, about 70, about 80, about 90, about 100, about 120, about 150, or about 180 minutes. Host cell populations can be

controlled in part by density of the host cells, or, in some embodiments, the host cell density in an inflow, e.g., 10^3 cells/ml, about 10^4 cells/ml, about 10^5 cells/ml, about 5- 10^5 cells/ml, about 10^6 cells/ml, about 5- 10^6 cells/ml, about 10^7 cells/ml, about 5- 10^7 cells/ml, about 10^8 cells/ml, about 5- 10^8 cells/ml, about 10^9 cells/ml, about $5\cdot 10^9$ cells/ml, about 10^{10} cells/ml, or about $5\cdot 10^{10}$ cells/ml.

Inteins

In some embodiments, as described in more detail below, an intein-N (intN) domain may be fused to the N-terminal portion of a first domain of a gene modifying polypeptide described herein, and an intein-C (intC) domain may be fused to the C-terminal portion of a second domain of a gene modifying polypeptide described herein for the joining of the N-terminal portion to the C-terminal portion, thereby joining the first and second domains. In some embodiments, the first and second domains are each independently chosen from a DNA binding domain, an RNA binding domain, an RT domain, and an endonuclease domain.

Inteins can occur as self-splicing protein intron (e.g., peptide), e.g., which ligates flanking N-terminal and C-terminal exteins (e.g., fragments to be joined). An intein may, in some instances, comprise a fragment of a protein that is able to excise itself and join the remaining fragments (the exteins) with a peptide bond in a process known as protein splicing. Inteins are also referred to as “protein introns.” The process of an intein excising itself and joining the remaining portions of the protein is herein termed “protein splicing” or “intein-mediated protein splicing.”

In some embodiments, an intein of a precursor protein (an intein containing protein prior to intein-mediated protein splicing) comes from two genes. Such intein is referred to herein as a split intein (e.g., split intein-N and split intein-C). Accordingly, an intein-based approach may be used to join a first polypeptide sequence and a second polypeptide sequence together. For example, in cyanobacteria, DnaE, the catalytic subunit a of DNA polymerase III, is encoded by two separate genes, dnaE-n and dnaE-c. An intein-N domain, such as that encoded by the dnaE-n gene, when situated as part of a first polypeptide sequence, may join the first polypeptide sequence with a second polypeptide sequence, wherein the second polypeptide sequence comprises an intein-C domain, such as that encoded by the dnaE-c gene. Accordingly, in some embodiments, a protein can be made by providing nucleic acid encoding the first and second polypeptide sequences (e.g., wherein a first nucleic acid molecule encodes the first polypeptide

sequence and a second nucleic acid molecule encodes the second polypeptide sequence), and the nucleic acid is introduced into the cell under conditions that allow for production of the first and second polypeptide sequences, and for joining of the first to the second polypeptide sequence via an intein-based mechanism.

Use of inteins for joining heterologous protein fragments is described, for example, in Wood et al., J. Biol. Chem.289(21); 14512-9 (2014) (incorporated herein by reference in its entirety). For example, when fused to separate protein fragments, the inteins IntN and IntC may recognize each other, splice themselves out, and/or simultaneously ligate the flanking N- and C-terminal exteins of the protein fragments to which they were fused, thereby reconstituting a full-length protein from the two protein fragments.

In some embodiments, a synthetic intein based on the dnaE intein, the Cfa-N (e.g., split intein-N) and Cfa-C (e.g., split intein-C) intein pair, is used. Examples of such inteins have been described, e.g., in Stevens et al., J Am Chem Soc. 2016 Feb. 24; 138(7):2162-5 (incorporated herein by reference in its entirety). Non-limiting examples of intein pairs that may be used in accordance with the present disclosure include: Cfa DnaE intein, Ssp GyrB intein, Ssp DnaX intein, Ter DnaE3 intein, Ter ThyX intein, Rma DnaB intein and Cne Prp8 intein (e.g., as described in U.S. Pat. No. 8,394,604, incorporated herein by reference.

In some embodiments involving a split Cas9, an intein-N domain and an intein-C domain may be fused to the N-terminal portion of the split Cas9 and the C-terminal portion of a split Cas9, respectively, for the joining of the N-terminal portion of the split Cas9 and the C-terminal portion of the split Cas9. For example, in some embodiments, an intein-N is fused to the C-terminus of the N-terminal portion of the split Cas9, i.e., to form a structure of N— [N-terminal portion of the split Cas9]-[intein-N]~ C. In some embodiments, an intein-C is fused to the N-terminus of the C-terminal portion of the split Cas9, i.e., to form a structure of N-[intein-C]~ [C-terminal portion of the split Cas9]-C. The mechanism of intein-mediated protein splicing for joining the proteins the inteins are fused to (e.g., split Cas9) is described in Shah et al., Chem Sci. 2014; 5(l):446-46l, incorporated herein by reference. Methods for designing and using inteins are known in the art and described, for example by WO2020051561, W02014004336, WO2017132580, US20150344549, and US20180127780, each of which is incorporated herein by reference in their entirety.

In some embodiments, a split refers to a division into two or more fragments. In some embodiments, a split Cas9 protein or split Cas9 comprises a Cas9 protein that is provided as an N-terminal fragment and a C-terminal fragment encoded by two separate nucleotide sequences. The polypeptides corresponding to the N-terminal portion and the C-terminal portion of the Cas9 protein may be spliced to form a reconstituted Cas9 protein. In embodiments, the Cas9 protein is divided into two fragments within a disordered region of the protein, e.g., as described in Nishimasu et al., Cell, Volume 156, Issue 5, pp. 935-949, 2014, or as described in Jiang et al. (2016) Science 351: 867-871 and PDB file: 5F9R (each of which is incorporated herein by reference in its entirety). A disordered region may be determined by one or more protein structure determination techniques known in the art, including, without limitation, X-ray crystallography, NMR spectroscopy, electron microscopy (e.g., cryoEM), and/or *in silico* protein modeling. In some embodiments, the protein is divided into two fragments at any C, T, A, or S, e.g., within a region of SpCas9 between amino acids A292- G364, F445-K483, or E565-T637, or at corresponding positions in any other Cas9, Cas9 variant (e.g., nCas9, dCas9), or other napDNAbp. In some embodiments, protein is divided into two fragments at SpCas9 T310, T313, A456, S469, or C574. In some embodiments, the process of dividing the protein into two fragments is referred to as splitting the protein.

In some embodiments, a protein fragment ranges from about 2-1000 amino acids (e.g., between 2-10, 10-50, 50-100, 100-200, 200-300, 300-400, 400-500, 500-600, 600-700, 700-800, 800-900, or 900-1000 amino acids) in length. In some embodiments, a protein fragment ranges from about 5-500 amino acids (e.g., between 5-10, 10-50, 50-100, 100-200, 200-300, 300-400, or 400-500 amino acids) in length. In some embodiments, a protein fragment ranges from about 20-200 amino acids (e.g., between 20-30, 30-40, 40-50, 50-100, or 100-200 amino acids) in length.

In some embodiments, a portion or fragment of a gene modifying polypeptide is fused to an intein. The nuclease can be fused to the N-terminus or the C-terminus of the intein. In some embodiments, a portion or fragment of a fusion protein is fused to an intein and fused to an AAV capsid protein. The intein, nuclease and capsid protein can be fused together in any arrangement (e.g., nuclease-intein-capsid, intein-nuclease-capsid, capsid-intein-nuclease, etc.). In some embodiments, the N-terminus of an intein is fused to the C-terminus of a fusion protein and the C-terminus of the intein is fused to the N-terminus of an AAV capsid protein.

In some embodiments, an endonuclease domain (e.g., a nickase Cas9 domain) is fused to intein-N and a polypeptide comprising an RT domain is fused to an intein-C.

Exemplary nucleotide and amino acid sequences of intein-N domains and compatible intein-C domains are provided below:

Additional domains

The gene modifying polypeptide can bind a target DNA sequence and template nucleic acid (e.g., template RNA), nick the target site, and write (e.g., reverse transcribe) the template into DNA, resulting in a modification of the target site. In some embodiments, additional domains may be added to the polypeptide to enhance the efficiency of the process. In some embodiments, the gene modifying polypeptide may contain an additional DNA ligation domain to join reverse transcribed DNA to the DNA of the target site. In some embodiments, the polypeptide may comprise a heterologous RNA-binding domain. In some embodiments, the polypeptide may comprise a domain having 5′ to 3′ exonuclease activity (e.g., wherein the 5′ to 3′ exonuclease activity increases repair of the alteration of the target site, e.g., in favor of alteration over the original genomic sequence). In some embodiments, the polypeptide may comprise a domain having 3′ to 5′ exonuclease activity, e.g., proof-reading activity. In some embodiments, the writing domain, e.g., RT domain, has 3′ to 5′ exonuclease activity, e.g., proof-reading activity.

Template nucleic acids

The gene modifying systems described herein can modify a host target DNA site using a template nucleic acid sequence. In some embodiments, the gene modifying systems described herein transcribe an RNA sequence template into host target DNA sites by target-primed reverse transcription (TPRT). By modifying DNA sequence(s) via reverse transcription of the RNA sequence template directly into the host genome, the gene modifying system can insert an object sequence into a target genome without the need for exogenous DNA sequences to be introduced into the host cell (unlike, for example, CRISPR systems), as well as eliminate an exogenous DNA insertion step. The gene modifying system can also delete a sequence from the target genome or introduce a substitution using an object sequence. Therefore, the gene modifying system provides a platform for the use of customized RNA sequence templates containing object sequences, e.g., sequences comprising heterologous gene coding and/or function information.

In some embodiments, the template nucleic acid comprises one or more sequence (e.g., 2 sequences) that binds the gene modifying polypeptide.

In some embodiments a system or method described herein comprises a single template nucleic acid (e.g., template RNA). In some embodiments a system or method described herein comprises a plurality of template nucleic acids (e.g., template RNAs). For example, a system described herein comprises a first RNA comprising (e.g., from 5´ to 3´) a sequence that binds the gene modifying polypeptide (e.g., the DNA-binding domain and/or the endonuclease domain, e.g., a gRNA) and a sequence that binds a target site (e.g., a second strand of a site in a target genome), and a second RNA (e.g., a template RNA) comprising (e.g., from 5´ to 3´) optionally a sequence that binds the gene modifying polypeptide (e.g., that specifically binds the RT domain), a heterologous object sequence, and a PBS sequence. In some embodiments, when the system comprises a plurality of nucleic acids, each nucleic acid comprises a conjugating domain. In some embodiments, a conjugating domain enables association of nucleic acid molecules, e.g., by hybridization of complementary sequences. For example, in some embodiments a first RNA comprises a first conjugating domain and a second RNA comprises a second conjugating domain, and the first and second conjugating domains are capable of hybridizing to one another, e.g., under stringent conditions. In some embodiments, the stringent conditions for hybridization include hybridization in 4x sodium chloride/sodium citrate (SSC), at about 65 C, followed by a wash in 1xSSC, at about 65 C.

In some embodiments, the template nucleic acid comprises RNA. In some embodiments, the template nucleic acid comprises DNA (e.g., single stranded or double stranded DNA).

In some embodiments, the template nucleic acid comprises one or more (e.g., 2) homology domains that have homology to the target sequence. In some embodiments, the homology domains are about 10-20, 20-50, or 50-100 nucleotides in length.

In some embodiments, a template RNA can comprise a gRNA sequence, e.g., to direct the gene modifying polypeptide to a target site of interest. In some embodiments, a template RNA comprises (e.g., from 5′ to 3′) (i) optionally a gRNA spacer that binds a target site (e.g., a second strand of a site in a target genome), (ii) optionally a gRNA scaffold that binds a polypeptide described herein (e.g., a gene modifying polypeptide or a Cas polypeptide), (iii) a heterologous object sequence comprising a mutation region (optionally the heterologous object

sequence comprises, from 5’ to 3’, a first homology region, a mutation region, and a second homology region), and (iv) a primer binding site (PBS) sequence comprising a 3′ target homology domain.

The template nucleic acid (e.g., template RNA) component of a genome editing system described herein typically is able to bind the gene modifying polypeptide of the system. In some embodiments the template nucleic acid (e.g., template RNA) has a 3′ region that is capable of binding a gene modifying polypeptide. The binding region, e.g., 3′ region, may be a structured RNA region, e.g., having at least 1, 2 or 3 hairpin loops, capable of binding the gene modifying polypeptide of the system. The binding region may associate the template nucleic acid (e.g., template RNA) with any of the polypeptide modules. In some embodiments, the binding region of the template nucleic acid (e.g., template RNA) may associate with an RNA-binding domain in the polypeptide. In some embodiments, the binding region of the template nucleic acid (e.g., template RNA) may associate with the reverse transcription domain of the gene modifying polypeptide (e.g., specifically bind to the RT domain). In some embodiments, the template nucleic acid (e.g., template RNA) may associate with the DNA binding domain of the polypeptide, e.g., a gRNA associating with a Cas9-derived DNA binding domain. In some embodiments, the binding region may also provide DNA target recognition, e.g., a gRNA hybridizing to the target DNA sequence and binding the polypeptide, e.g., a Cas9 domain. In some embodiments, the template nucleic acid (e.g., template RNA) may associate with multiple components of the polypeptide, e.g., DNA binding domain and reverse transcription domain.

In some embodiments the template RNA has a poly-A tail at the 3´ end. In some embodiments the template RNA does not have a poly-A tail at the 3´ end.

In some embodiments, the template nucleic acid is a template RNA. In some embodiments, the template RNA comprises one or more modified nucleotides. For example, in some embodiments, the template RNA comprises one or more deoxyribonucleotides. In some embodiments, regions of the template RNA are replaced by DNA nucleotides, e.g., to enhance stability of the molecule. For example, the 3´ end of the template may comprise DNA nucleotides, while the rest of the template comprises RNA nucleotides that can be reverse transcribed. For instance, in some embodiments, the heterologous object sequence is primarily or wholly made up of RNA nucleotides (e.g., at least 90%, 95%, 98%, or 99% RNA nucleotides). In some embodiments, the PBS sequence is primarily or wholly made up of DNA

nucleotides (e.g., at least 90%, 95%, 98%, or 99% DNA nucleotides). In other embodiments, the heterologous object sequence for writing into the genome may comprise DNA nucleotides. In some embodiments, the DNA nucleotides in the template are copied into the genome by a domain capable of DNA-dependent DNA polymerase activity. In some embodiments, the DNA-dependent DNA polymerase activity is provided by a DNA polymerase domain in the polypeptide. In some embodiments, the DNA-dependent DNA polymerase activity is provided by a reverse transcriptase domain that is also capable of DNA-dependent DNA polymerization, e.g., second strand synthesis. In some embodiments, the template molecule is composed of only DNA nucleotides.

In some embodiments, a system described herein comprises two nucleic acids which together comprise the sequences of a template RNA described herein. In some embodiments, the two nucleic acids are associated with each other non-covalently, e.g., directly associated with each other (e.g., via base pairing), or indirectly associated as part of a complex comprising one or more additional molecule.

A template RNA described herein may comprise, from 5’ to 3’: (1) a gRNA spacer; (2) a gRNA scaffold; (3) heterologous object sequence (4) a primer binding site (PBS) sequence. Each of these components is now described in more detail.

gRNA spacer and gRNA scaffold

A template RNA described herein may comprise a gRNA spacer that directs the gene modifying system to a target nucleic acid, and a gRNA scaffold that promotes association of the template RNA with the Cas domain of the gene modifying polypeptide. The systems described herein can also comprise a gRNA that is not part of a template nucleic acid. For example, a gRNA that comprises a gRNA spacer and gRNA scaffold, but not a heterologous object sequence or a PBS sequence, can be used, e.g., to induce second strand nicking, e.g., as described in the section herein entitled “Second Strand Nicking”.

In some embodiments, the gRNA is a short synthetic RNA composed of a scaffold sequence that participates in CRISPR-associated protein binding and a user-defined ~20 nucleotide targeting sequence for a genomic target. The structure of a complete gRNA was described by Nishimasu et al. Cell 156, P935-949 (2014). The gRNA (also referred to as sgRNA for single-guide RNA) consists of crRNA- and tracrRNA-derived sequences connected by an

artificial tetraloop. The crRNA sequence can be divided into guide (20 nt) and repeat (12 nt) regions, whereas the tracrRNA sequence can be divided into anti-repeat (14 nt) and three tracrRNA stem loops (Nishimasu et al. Cell 156, P935-949 (2014)). In practice, guide RNA sequences are generally designed to have a length of between 17 – 24 nucleotides (e.g., 19, 20, or 21 nucleotides) and be complementary to a targeted nucleic acid sequence. Custom gRNA generators and algorithms are available commercially for use in the design of effective guide RNAs. In some embodiments, the gRNA comprises two RNA components from the native CRISPR system, e.g. crRNA and tracrRNA. As is well known in the art, the gRNA may also comprise a chimeric, single guide RNA (sgRNA) containing sequence from both a tracrRNA (for binding the nuclease) and at least one crRNA (to guide the nuclease to the sequence targeted for editing/binding). Chemically modified sgRNAs have also been demonstrated to be effective for use with CRISPR-associated proteins; see, for example, Hendel et al. (2015) Nature Biotechnol., 985 – 991. In some embodiments, a gRNA spacer comprises a nucleic acid sequence that is complementary to a DNA sequence associated with a target gene.

In some embodiments, the region of the template nucleic acid, e.g., template RNA, comprising the gRNA adopts an underwound ribbon-like structure of gRNA bound to target DNA (e.g., as described in Mulepati et al. Science 19 Sep 2014:Vol. 345, Issue 6203, pp. 1479-1484). Without wishing to be bound by theory, this non-canonical structure is thought to be facilitated by rotation of every sixth nucleotide out of the RNA-DNA hybrid. Thus, in some embodiments, the region of the template nucleic acid, e.g., template RNA, comprising the gRNA may tolerate increased mismatching with the target site at some interval, e.g., every sixth base. In some embodiments, the region of the template nucleic acid, e.g., template RNA, comprising the gRNA comprising homology to the target site may possess wobble positions at a regular interval, e.g., every sixth base, that do not need to base pair with the target site.

In some embodiments, the template nucleic acid (e.g., template RNA) has at least 15, 16, 17, 18, 19, 20, 21, 22, 23, or 24 bases of at least 80%, 85%, 90%, 95%, 99%, or 100% homology to the target site, e.g., at the 5’ end, e.g., comprising a gRNA spacer sequence of length appropriate to the Cas9 domain of the gene modifying polypeptide (Table 8).

In some embodiments, a Cas9 derivative with enhanced activity may be used in the gene modification polypeptide. In some embodiments, a Cas9 derivative may comprise mutations that improve activity of the HNH endonuclease domain, e.g., SpyCas9 R221K, N394K, or mutations

that improve R-loop formation, e.g., SpyCas9 L1245V, or comprise a combination of such mutations, e.g., SpyCas9 R221K/N394K, SpyCas9 N394K/L1245V, SpyCas9 R221K/L1245V, or SpyCas9 R221K/N394K/L1245V (see, e.g., Spencer and Zhang Sci Rep 7:16836 (2017), the Cas9 derivatives and comprising mutations of which are incorporated herein by reference). In some embodiments, a Cas9 derivative may comprise one or more types of mutations described herein, e.g., PAM-modifying mutations, protein stabilizing mutations, activity enhancing mutations, and/or mutations partially or fully inactivating one or two endonuclease domains relative to the parental enzyme (e.g., one or more mutations to abolish endonuclease activity towards one or both strands of a target DNA, e.g., a nickase or catalytically dead enzyme). In some embodiments, a Cas9 enzyme used in a system described herein may comprise mutations that confer nickase activity toward the enzyme (e.g., SpyCas9 N863A or H840A) in addition to mutations improving catalytic efficiency (e.g., SpyCas9 R221K, N394K, and/or L1245V). In some embodiments, a Cas9 enzyme used in a system described herein is a SpyCas9 enzyme or derivative that further comprises an N863A mutation to confer nickase activity in addition to R221K and N394K mutations to improve catalytic efficiency.

Table 12 provides parameters to define components for designing gRNA and/or Template RNAs to apply Cas variants listed in Table 8 for gene modifying. The cut site indicates the validated or predicted protospacer adjacent motif (PAM) requirements, validated or predicted location of cut site (relative to the most upstream base of the PAM site). The gRNA for a given enzyme can be assembled by concatenating the crRNA, Tetraloop, and tracrRNA sequences, and further adding a 5′ spacer of a length within Spacer (min) and Spacer (max) that matches a protospacer at a target site. Further, the predicted location of the ssDNA nick at the target is important for designing a PBS sequence of a Template RNA that can anneal to the sequence immediately 5′ of the nick in order to initiate target primed reverse transcription. In some embodiments, a gRNA scaffold described herein comprises a nucleic acid sequence comprising, in the 5’ to 3’ direction, a crRNA of Table 12, a tetraloop from the same row of Table 12, and a tracrRNA from the same row of Table 12, or a sequence having at least 70%, 80%, 85%, 90%, 95%, or 99% identity thereto. In some embodiments, the gRNA or template RNA comprising the scaffold further comprises a gRNA spacer having a length within the Spacer (min) and Spacer (max) indicated in the same row of Table 12. In some embodiments, the gRNA or template RNA having a sequence according to Table 12 is comprised by a system that further

comprises a gene modifying polypeptide, wherein the gene modifying polypeptide comprises a Cas domain described in the same row of Table 12.

Table 12 Parameters to define components for designing gRNA and/or Template RNAs to apply Cas variants listed in Table 8 in gene modifying systems.

Herein, when an RNA sequence (e.g., a template RNA sequence) is said to comprise a particular sequence (e.g., a sequence of Table 12 or a portion thereof) that comprises thymine (T), it is of course understood that the RNA sequence may (and frequently does) comprise uracil (U) in place of T. For instance, the RNA sequence may comprise U at every position shown as T in the sequence in Table 12. More specifically, the present disclosure provides an RNA sequence according to every gRNA scaffold sequence of Table 12, wherein the RNA sequence has a U in place of each T in the sequence in Table 12. Additionally, it is understood that terminal Us and Ts may optionally be added or removed from tracrRNA sequences and may be modified or unmodified when provided as RNA. Without wishing to be bound by example, versions of gRNA scaffold sequences alternative to those exemplified in Table 12 may also function with the different Cas9 enzymes or derivatives thereof exemplified in Table 8, e.g., alternate gRNA scaffold sequences with nucleotide additions, substitutions, or deletions, e.g., sequences with stem-loop structures added or removed. It is contemplated herein that the gRNA scaffold sequences represent a component of gene modifying systems that can be similarly optimized for a given system, Cas-RT fusion polypeptide, indication, target mutation, template RNA, or delivery vehicle.

Heterologous object sequence

A template RNA described herein may comprise a heterologous object sequence that the gene modifying polypeptide can use as a template for reverse transcription, to write a desired sequence into the target nucleic acid. In some embodiments, the heterologous object sequence comprises, from 5' to 3', a post-edit homology region, the mutation region, and a pre-edit homology region. Without wishing to be bound by theory, an RT performing reverse transcription on the template RNA first reverse transcribes the pre-edit homology region, then the mutation region, and then the post-edit homology region, thereby creating a DNA strand comprising the desired mutation with a homology region on either side.

In some embodiments, the heterologous object sequence is at least 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100, 120, 140, 160, 180, 200, 500, or 1,000 nucleotides (nts) in length, or at least 1, 1.5, 2, 2.5, 3, 3.5, 4, 4.5, 5, 5.5, 6, 6.5, 7, 7.5, 8, 8.5, 9, 9.5, or 10 kilobases in length. In some embodiments, the heterologous object sequence is no more than 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100, 120, 140, 160, 180, 200, 500, 1,000, or 2000 nucleotides (nts) in length, or no more than 20, 15, 10, 9, 8, 7, 6, 5, 4, or 3 kilobases in length. In some embodiments, the heterologous object sequence is 30-1000, 40-1000, 50-1000, 60-1000, 70-1000, 74-1000, 75-1000, 76-1000, 77-1000, 78-1000, 79-1000, 80-1000, 85-1000, 90-1000, 100-1000, 120-1000, 140-1000, 160-1000, 180-1000, 200-1000, 500-1000, 30-500, 40-500, 50-500, 60-500, 70-500, 74-500, 75-500, 76-500, 77-500, 78-500, 79-500, 80-500, 85-500, 90-500, 100-500, 120-500, 140-500, 160-500, 180-500, 200-500, 30-200, 40-200, 50-200, 60-200, 70-200, 74-200, 75-200, 76-200, 77-200, 78-200, 79-200, 80-200, 85-200, 90-200, 100-200, 120-200, 140-200, 160-200, 180-200, 30-100, 40-100, 50-100, 60-100, 70-100, 74-100, 75-100, 76-100, 77-100, 78-100, 79-100, 80-100, 85-100, or 90-100 nucleotides (nts) in length, or 1-20, 1-15, 1-10, 1-9, 1-8, 1-7, 1-6, 1-5, 1-4, 1-3, 1-2, 2-20, 2-15, 2-10, 2-9, 2-8, 2-7, 2-6, 2-5, 2-4, 2-3, 3-20, 3-15, 3-10, 3-9, 3-8, 3-7, 3-6, 3-5, 3-4, 4-20, 4-15, 4-10, 4-9, 4-8, 4-7, 4-6, 4-5, 5-20, 5-15, 5-10, 5-9, 5-8, 5-7, 5-6, 6-20, 6-15, 6-10, 6-9, 6-8, 6-7, 7-20, 7-15, 7-10, 7-9, 7-8, 8-20, 8-15, 8-

10, 8-9, 9-20, 9-15, 9-10, 10-15, 10-20, or 15-20 kilobases in length. In some embodiments, the heterologous object sequence is 10-100, 10-90, 10-80, 10-70, 10-60, 10-50, 10-40, 10-30, or 10-20 nt in length, e.g., 10-80, 10-50, or 10-20 nt in length, e.g., about10-20 nt in length. In some embodiments, the heterologous object sequence is 8-30, 9-25, 10-20, 11-16, or 12-15 nucleotides in length, e.g., is 11-16 nt in length. Without wishing to be bound by theory, in some embodiments, a larger insertion size, larger region of editing (e.g., the distance between a first edit/substitution and a second edit/substitution in the target region), and/or greater number of desired edits (e.g., mismatches of the heterologous object sequence to the target genome), may result in a longer optimal heterologous object sequence.

In certain embodiments, the template nucleic acid comprises a customized RNA sequence template which can be identified, designed, engineered and constructed to contain sequences altering or specifying host genome function, for example by introducing a heterologous coding region into a genome; affecting or causing exon structure/alternative splicing, e.g., leading to exon skipping of one or more exons; causing disruption of an endogenous gene, e.g., creating a genetic knockout; causing transcriptional activation of an endogenous gene; causing epigenetic regulation of an endogenous DNA; causing up-regulation of one or more operably linked genes, e.g., leading to gene activation or overexpression; causing down-regulation of one or more operably linked genes, e.g., creating a genetic knock-down; etc. In certain embodiments, a customized RNA sequence template can be engineered to contain sequences coding for exons and/or transgenes, provide binding sites for transcription factor activators, repressors, enhancers, etc., and combinations thereof. In some embodiments, a customized template can be engineered to encode a nucleic acid or peptide tag to be expressed in an endogenous RNA transcript or endogenous protein operably linked to the target site. In other embodiments, the coding sequence can be further customized with splice donor sites, splice acceptor sites, or poly-A tails.

The template nucleic acid (e.g., template RNA) of the system typically comprises an object sequence (e.g., a heterologous object sequence) for writing a desired sequence into a target DNA. The object sequence may be coding or non-coding. The template nucleic acid (e.g., template RNA) can be designed to result in insertions, mutations, or deletions at the target DNA locus. In some embodiments, the template nucleic acid (e.g., template RNA) may be designed to cause an insertion in the target DNA. For example, the template nucleic acid (e.g., template RNA) may contain a heterologous sequence, wherein the reverse transcription will result in

insertion of the heterologous sequence into the target DNA. In other embodiments, the RNA template may be designed to introduce a deletion into the target DNA. For example, the template nucleic acid (e.g., template RNA) may match the target DNA upstream and downstream of the desired deletion, wherein the reverse transcription will result in the copying of the upstream and downstream sequences from the template nucleic acid (e.g., template RNA) without the intervening sequence, e.g., causing deletion of the intervening sequence. In other embodiments, the template nucleic acid (e.g., template RNA) may be designed to introduce an edit into the target DNA. For example, the template RNA may match the target DNA sequence with the exception of one or more nucleotides, wherein the reverse transcription will result in the copying of these edits into the target DNA, e.g., resulting in mutations, e.g., transition or transversion mutations.

In some embodiments, writing of an object sequence into a target site results in the substitution of nucleotides, e.g., where the full length of the object sequence corresponds to a matching length of the target site with one or more mismatched bases. In some embodiments, a heterologous object sequence may be designed such that a combination of sequence alterations may occur, e.g., a simultaneous addition and deletion, addition and substitution, or deletion and substitution.

In some embodiments, the heterologous object sequence may contain an open reading frame or a fragment of an open reading frame. In some embodiments the heterologous object sequence has a Kozak sequence. In some embodiments the heterologous object sequence has an internal ribosome entry site. In some embodiments the heterologous object sequence has a self-cleaving peptide such as a T2A or P2A site. In some embodiments the heterologous object sequence has a start codon. In some embodiments the template RNA has a splice acceptor site. In some embodiments the template RNA has a splice donor site. Exemplary splice acceptor and splice donor sites are described in WO2016044416, incorporated herein by reference in its entirety. Exemplary splice acceptor site sequences are known to those of skill in the art. In some embodiments the template RNA has a microRNA binding site downstream of the stop codon. In some embodiments the template RNA has a polyA tail downstream of the stop codon of an open reading frame. In some embodiments the template RNA comprises one or more exons. In some embodiments the template RNA comprises one or more introns. In some embodiments the template RNA comprises a eukaryotic transcriptional terminator. In some embodiments the

template RNA comprises an enhanced translation element or a translation enhancing element. In some embodiments the RNA comprises the human T-cell leukemia virus (HTLV-1) R region. In some embodiments the RNA comprises a posttranscriptional regulatory element that enhances nuclear export, such as that of Hepatitis B Virus (HPRE) or Woodchuck Hepatitis Virus (WPRE).

In some embodiments, the heterologous object sequence may contain a non-coding sequence. For example, the template nucleic acid (e.g., template RNA) may comprise a regulatory element, e.g., a promoter or enhancer sequence or miRNA binding site. In some embodiments, integration of the object sequence at a target site will result in upregulation of an endogenous gene. In some embodiments, integration of the object sequence at a target site will result in downregulation of an endogenous gene. In some embodiments the template nucleic acid (e.g., template RNA) comprises a tissue specific promoter or enhancer, each of which may be unidirectional or bidirectional. In some embodiments the promoter is an RNA polymerase I promoter, RNA polymerase II promoter, or RNA polymerase III promoter. In some embodiments the promoter comprises a TATA element. In some embodiments the promoter comprises a B recognition element. In some embodiments the promoter has one or more binding sites for transcription factors.

In some embodiments, the template nucleic acid (e.g., template RNA) comprises a site that coordinates epigenetic modification. In some embodiments, the template nucleic acid (e.g., template RNA) comprises a chromatin insulator. For example, the template nucleic acid (e.g., template RNA) comprises a CTCF site or a site targeted for DNA methylation.

In some embodiments, the template nucleic acid (e.g., template RNA) comprises a gene expression unit composed of at least one regulatory region operably linked to an effector sequence. The effector sequence may be a sequence that is transcribed into RNA (e.g., a coding sequence or a non-coding sequence such as a sequence encoding a micro RNA).

In some embodiments, the heterologous object sequence of the template nucleic acid (e.g., template RNA) is inserted into a target genome in an endogenous intron. In some embodiments, the heterologous object sequence of the template nucleic acid (e.g., template RNA) is inserted into a target genome and thereby acts as a new exon. In some embodiments, the insertion of the heterologous object sequence into the target genome results in replacement of a natural exon or the skipping of a natural exon.

The template nucleic acid (e.g., template RNA) can be designed to result in insertions, mutations, or deletions at the target DNA locus. In some embodiments, the template nucleic acid (e.g., template RNA) may be designed to cause an insertion in the target DNA. For example, the template nucleic acid (e.g., template RNA) may contain a heterologous object sequence, wherein the reverse transcription will result in insertion of the heterologous object sequence into the target DNA. In other embodiments, the RNA template may be designed to write a deletion into the target DNA. For example, the template nucleic acid (e.g., template RNA) may match the target DNA upstream and downstream of the desired deletion, wherein the reverse transcription will result in the copying of the upstream and downstream sequences from the template nucleic acid (e.g., template RNA) without the intervening sequence, e.g., causing deletion of the intervening sequence. In other embodiments, the template nucleic acid (e.g., template RNA) may be designed to write an edit into the target DNA. For example, the template RNA may match the target DNA sequence with the exception of one or more nucleotides, wherein the reverse transcription will result in the copying of these edits into the target DNA, e.g., resulting in mutations, e.g., transition or transversion mutations.

In some embodiments, the pre-edit homology domain comprises a nucleic acid sequence having 100% sequence identity with a nucleic acid sequence comprised in a target nucleic acid molecule.

In some embodiments, the post-edit homology domain comprises a nucleic acid sequence having 100% sequence identity with a nucleic acid sequence comprised in a target nucleic acid molecule.

PBS sequence

In some embodiments, a template nucleic acid (e.g., template RNA) comprises a PBS sequence. In some embodiments, a PBS sequence is disposed 3′ of the heterologous object sequence and is complementary to a sequence adjacent to a site to be modified by a system described herein, or comprises no more than 1, 2, 3, 4, or 5 mismatches to a sequence complementary to the sequence adjacent to a site to be modified by the system/gene modifying polypeptide. In some embodiments, the PBS sequence binds within 1, 2, 3, 4, 5, 6, 7, 8, 9, or 10 nucleotides of a nick site in the target nucleic acid molecule. In some embodiments, binding of the PBS sequence to the target nucleic acid molecule permits initiation of target-primed reverse transcription (TPRT), e.g., with the 3′ homology domain acting as a primer for TPRT. In some

embodiments, the PBS sequence is 3-5, 5-10, 10-30, 10-25, 10-20, 10-19, 10-18, 10-17, 10-16, 10-15, 10-14, 10-13, 10-12, 10-11, 11-30, 11-25, 11-20, 11-19, 11-18, 11-17, 11-16, 11-15, 11-14, 11-13, 11-12, 12-30, 12-25, 12-20, 12-19, 12-18, 12-17, 12-16, 12-15, 12-14, 12-13, 13-30, 13-25, 13-20, 13-19, 13-18, 13-17, 13-16, 13-15, 13-14, 14-30, 14-25, 14-20, 14-19, 14-18, 14-17, 14-16, 14-15, 15-30, 15-25, 15-20, 15-19, 15-18, 15-17, 15-16, 16-30, 16-25, 16-20, 16-19, 16-18, 16-17, 17-30, 17-25, 17-20, 17-19, 17-18, 18-30, 18-25, 18-20, 18-19, 19-30, 19-25, 19-20, 20-30, 20-25, or 25-30 nucleotides in length, e.g., 10-17, 12-16, or 12-14 nucleotides in length. In some embodiments, the PBS sequence is 5-20, 8-16, 8-14, 8-13, 9-13, 9-12, or 10-12 nucleotides in length, e.g., 9-12 nucleotides in length.

The template nucleic acid (e.g., template RNA) may have some homology to the target DNA. In some embodiments, the template nucleic acid (e.g., template RNA) PBS sequence domain may serve as an annealing region to the target DNA, such that the target DNA is positioned to prime the reverse transcription of the template nucleic acid (e.g., template RNA). In some embodiments the template nucleic acid (e.g., template RNA) has at least 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 20, 25, 30, 35, 40, 45, 50, 60, 70, 80, 90, 100, 110, 120, 130, 140, 150, 175, 200 or more bases of exact homology to the target DNA at the 3′ end of the RNA. In some embodiments the template nucleic acid (e.g., template RNA) has at least 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 20, 25, 30, 35, 40, 45, 50, 60, 70, 80, 90, 100, 110, 120, 130, 140, 150, 175, 200 or more bases of at least 50%, 60%, 70%, 80%, 85%, 90%, 95%, 97%, 98%, 99% or 100% homology to the target DNA, e.g., at the 5′ end of the template nucleic acid (e.g., template RNA).

Exemplary template sequences

In some embodiments of the systems and methods herein, the template RNA comprises a gRNA spacer comprising the core nucleotides of a gRNA spacer sequence of Table 1A, Table 1B, Table 1C, or Table 1D. In some embodiments, the gRNA spacer additionally comprises one or more (e.g., 2, 3, or all) consecutive nucleotides starting with the 3’ end of the flanking nucleotides of the gRNA spacer. In some embodiments, the template RNA comprising a sequence of Table 11A, Table 1B, Table 1C, or Table 1D is comprised by a system that further comprises a gene modifying polypeptide having an RT domain listed in the same line of Table 11A, Table 1B, Table 1C, or Table 1D. RT domain amino acid sequences can be found, e.g., in Table 6 herein.

Table 1A: Exemplary gRNA spacer Cas pairs for correcting the pathogenic R408W mutation

Table 1A provides a gRNA database for correcting the pathogenic R408W mutation in PAH. List of spacers, PAMs, and Cas variants for generating a nick at an appropriate position to enable installation of a desired genomic edit with a gene modifying system. The spacers in this table are designed to be used with a gene modifying polypeptide comprising a nickase variant of the Cas species indicated in the table. Tables 2A, 3A, and 4A detail the other components of the system and are organized such that the ID number shown here in Column 1 ("ID") is meant to correspond to the same ID number in Tables 2A, 3A, and 4A.

Table 1B: Exemplary gRNA spacer Cas pairs for correcting the pathogenic R261Q mutation

Table 1B provides a gRNA database for correcting the pathogenic R261Q mutation in PAH. List of spacers, PAMs, and Cas variants for generating a nick at an appropriate position to enable installation of a desired genomic edit with a gene modifying system. The spacers in this table are designed to be used with a gene modifying polypeptide comprising a nickase variant of the Cas species indicated in the table. Tables 2B, 3B, and 4B detail the other components of the system and are organized such that the ID number shown here in Column 1 (“ID”) is meant to correspond to the same ID number in Tables 2B, 2B, and 4B.

Table 1C: Exemplary gRNA spacer Cas pairs for correcting the pathogenic R243Q mutation

Table 1C provides a gRNA database for correcting the pathogenic R243Q mutation in PAH. List of spacers, PAMs, and Cas variants for generating a nick at an appropriate position to enable installation of a desired genomic edit with a gene modifying system. The spacers in this table are designed to be used with a gene modifying polypeptide comprising a nickase variant of the Cas species indicated in the table. Tables 2C, 3C, and 4C detail the other components of the system and are organized such that the ID number shown here in Column 1 ("ID") is meant to correspond to the same ID number in Tables 2C, 2C, and 4C.

Table 1D: Exemplary gRNA spacer Cas pairs for correcting the pathogenic IVS10-11G>A mutation

Table 1D provides a gRNA database for correcting the pathogenic IVS10-11G>A mutation in PAH. List of spacers, PAMs, and Cas variants for generating a nick at an appropriate position to enable installation of a desired genomic edit with a gene modifying system. The spacers in this table are designed to be used with a gene modifying polypeptide comprising a nickase variant of the Cas species indicated in the table. Tables 2D, 3D, and 4D detail the other components of the system and are organized such that the ID number shown here in Column 1 ("ID") is meant to correspond to the same ID number in Tables 2D, 2D, and 4D.

In the exemplary template sequences provided herein, capital letters indicate "core nucleotides" while lower case letters indicate "flanking nucleotides." Herein, when an RNA sequence (e.g., a template RNA sequence) is said to comprise a particular sequence (e.g., a sequence of Tables 1A, 1B, 1C, or 1D or a portion thereof) that comprises thymine (T), it is of course understood that the RNA sequence may (and frequently does) comprise uracil (U) in place of T. For instance, the RNA sequence may comprise U at every position shown as T in the sequence in Tables 1A, 1B, 1C, or 1D. More specifically, the present disclosure provides an RNA sequence according to every gRNA spacer sequence shown in Tables 1A, 1B, 1C, or 1D, wherein the RNA sequence has a U in place of each T in the sequence in Tables 1A, 1B, 1C, or 1D.

In some embodiments of the systems and methods herein, the heterologous object sequence comprises the core nucleotides of an RT template sequence from Table 3A, Table 3B, Table 3C, or Table 3D. In some embodiments, the heterologous object sequence additionally comprises one or more (e.g., 2, 3, 4, 5, 10, 20, 30, 40, or all) consecutive nucleotides starting with the 3' end of the flanking nucleotides of the RT template sequence. In some embodiments, the heterologous object sequence comprises the core nucleotides of the RT template sequence of Table 3A, Table 3B, Table 3C, or Table 3D that corresponds to the gRNA spacer sequence. In the context of the sequence tables, a first component "corresponds to" a second component when both components have the same ID number in the referenced table. For example, for a gRNA spacer of ID #1, the *corresponding* RT template would be the RT template also having ID #1 in a table referencing the same mutation. In some embodiments, the heterologous object sequence

additionally comprises one or more consecutive nucleotides starting with the 3' end of the flanking nucleotides of the RT template sequence.

In some embodiments, the primer binding site (PBS) sequence has a sequence comprising the core nucleotides of a PBS sequence from the same row of Table 3A, Table 3B, Table 3C, or Table 3D as the RT template sequence. In some embodiments, the PBS sequence additionally comprises one or more (e.g., 1, 2, 3, 4, 5, 6, 7, or all) consecutive nucleotides starting with the 5' end of the flanking nucleotides of the primer region.

Table 3A: Exemplary RT sequence (heterologous object sequence) and PBS sequence pairs

Table 3A provides exemplified PBS sequences and heterologous object sequences (reverse transcription template regions) of a template RNA for correcting the pathogenic R408W mutation in PAH. The gRNA spacers from Table 1A were filtered, e.g., filtered by occurrence within 15 nt of the desired editing location and use of a Tier 1 Cas enzyme. PBS sequences and heterologous object sequences (reverse transcription template regions) were designed relative to the nick site directed by the cognate gRNA from Table 1A, as described in this application. For exemplification, these regions were designed to be 8-17 nt (priming) and 1-50 nt extended beyond the location of the edit (RT). Without wishing to be limited by example, given variability of length, sequences are provided that use the maximum length parameters and comprise all templates of shorter length within the given parameters. Sequences are shown with uppercase letters indicating core sequence and lowercase letters indicating flanking sequence that may be truncated within the described length parameters.

Table 3B: Exemplary RT sequence (heterologous object sequence) and PBS sequence pairs

Table 3B provides exemplified PBS sequences and heterologous object sequences (reverse transcription template regions) of a template RNA for correcting the pathogenic R261Q mutation in PAH. The gRNA spacers from Table 1B were filtered, e.g., filtered by occurrence within 15 nt of the desired editing location and use of a Tier 1 Cas enzyme. PBS sequences and heterologous object sequences (reverse transcription template regions) were designed relative to the nick site directed by the cognate gRNA from Table 1B, as described in this application. For exemplification, these regions were designed to be 8-17 nt

(priming) and 1-50 nt extended beyond the location of the edit (RT). Without wishing to be limited by example, given variability of length, sequences are provided that use the maximum length parameters and comprise all templates of shorter length within the given parameters. Sequences are shown with uppercase letters indicating core sequence and lowercase letters indicating flanking sequence that may be truncated within the described length parameters.

Table 3C: Exemplary RT sequence (heterologous object sequence) and PBS sequence pairs

Table 3C provides exemplified PBS sequences and heterologous object sequences (reverse transcription template regions) of a template RNA for correcting the pathogenic R243Q mutation in PAH. The gRNA spacers from Table 1C were filtered, e.g., filtered by occurrence within 15 nt of the desired editing location and use of a Tier 1 Cas enzyme. PBS sequences and heterologous object sequences (reverse transcription template regions) were designed relative to the nick site directed by the cognate gRNA from

Table 1C, as described in this application. For exemplification, these regions were designed to be 8-17 nt (priming) and 1-50 nt extended beyond the location of the edit (RT). Without wishing to be limited by example, given variability of length, sequences are provided that use the maximum length parameters and comprise all templates of shorter length within the given parameters. Sequences are shown with uppercase letters indicating core sequence and lowercase letters indicating flanking sequence that may be truncated within the described length parameters.

Table 3D: Exemplary RT sequence (heterologous object sequence) and PBS sequence pairs

Table 3D provides exemplified PBS sequences and heterologous object sequences (reverse transcription template regions) of a template RNA for correcting the pathogenic IVS10-11G>A mutation in PAH. The gRNA spacers from Table 1D were filtered, e.g., filtered by occurrence within 15 nt of the desired editing location and use of a Tier 1 Cas enzyme. PBS sequences and heterologous object sequences (reverse transcription template regions) were designed relative to the nick site directed by the cognate gRNA from Table 1D, as described in this application. For exemplification, these regions were designed to be 8-17 nt (priming) and 1-50 nt extended beyond the location of the edit (RT). Without wishing to be limited by example, given variability of length, sequences are provided that use the maximum length parameters and comprise all templates of shorter length within the given parameters. Sequences are shown with uppercase letters indicating core sequence and lowercase letters indicating flanking sequence that may be truncated within the described length parameters.

Capital letters indicate “core nucleotides” while lower case letters indicate “flanking nucleotides.” Herein, when an RNA sequence (e.g., a template RNA sequence) is said to comprise a particular sequence (e.g., a sequence of Table 3A, Table 3B, Table 3C, or Table 3D or a portion thereof) that comprises thymine (T), it is of course understood that the RNA sequence may (and frequently does) comprise uracil (U) in place of T. For instance, the RNA sequence may comprise U at every position shown as T in the sequence in Table 3A, Table 3B, Table 3C, or Table 3D. More specifically, the present disclosure provides an RNA sequence according to every heterologous object sequence and PBS sequence shown in Table 3A, Table 3B, Table 3C, or Table 3D, wherein the RNA sequence has a U in place of each T in the sequence of Table 3A, Table 3B, Table 3C, or Table 3D.

In some embodiments of the systems and methods herein, the template RNA comprises a gRNA scaffold (e.g., that binds a gene modifying polypeptide, e.g., a Cas polypeptide) that comprises a sequence of a gRNA scaffold of Table 12. In some embodiments, the gRNA scaffold comprises a sequence having at least 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, or 99% identity to a gRNA scaffold of Table 12. In some embodiments, the gRNA scaffold comprises a sequence of a scaffold region of Table 12 that corresponds to the RT template sequence, the spacer sequence, or both, or a sequence having at least 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, or 99% identity thereto.

In some embodiments of the systems and methods herein, the system further comprises a second strand-targeting gRNA that directs a nick to the second strand of the human PAH gene. In some embodiments, the second strand-targeting gRNA comprises a left gRNA spacer sequence or a right gRNA spacer sequence from Table 2A, Table 2B, Table 2C, or Table 2D. In some embodiments, the gRNA spacer additionally comprises one or more (e.g., 2, 3, or all) consecutive nucleotides starting with the 3’ end of the flanking nucleotides of the left gRNA spacer sequence or right gRNA spacer sequence. In some embodiments, the second strand-

targeting gRNA comprises a sequence comprising the core nucleotides of a second nick gRNA sequence from Table 4A, Table 4B, Table 4C, or Table 4D, or a sequence having at least 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, or 99% identity thereto. In some embodiments, the second nick gRNA sequence additionally comprises one or more consecutive nucleotides starting with the 3' end of the flanking nucleotides of the second nick gRNA sequence. In some embodiments, the second nick gRNA comprises a gRNA scaffold sequence that is orthogonal to the Cas domain of the gene modifying polypeptide. In some embodiments, the second nick gRNA comprises a gRNA scaffold sequence of Table 12.

Table 2A: Exemplary left gRNA spacer and right gRNA spacer pairs

Table 2A provides exemplified second-nick gRNA species for optional use for correcting the pathogenic R408W mutation in PAH. The gRNA spacers from Table 1A were filtered, e.g., filtered by occurrence within 15 nt of the desired editing location and use of a Tier 1 Cas enzyme. Second-nick gRNAs were generated by searching the opposite strand of DNA in the regions -40 to -140 ("left") and +40 to +140 ("right"), relative to the first nick site defined by the first gRNA, for the PAM utilized by the corresponding Cas variant. One exemplary spacer is shown for each side of the target nick site.

Table 2B: Exemplary left gRNA spacer and right gRNA spacer pairs

Table 2B provides exemplified second-nick gRNA species for optional use for correcting the pathogenic R261Q mutation in PAH. The gRNA spacers from Table 1B were filtered, e.g., filtered by occurrence within 15 nt of the desired editing location and use of a Tier 1 Cas enzyme. Second-nick gRNAs were generated by searching the opposite strand of DNA in the regions -40 to -140 (“left”) and +40 to +140 (“right”), relative to the first nick site defined by the first gRNA, for the PAM utilized by the corresponding Cas variant. One exemplary spacer is shown for each side of the target nick site.

ID	Left gRNA spacer	SEQ ID NO	Left PAM	Right gRNA spacer	SEQ ID NO	Right PAM

Table 2C: Exemplary left gRNA spacer and right gRNA spacer pairs

Table 2C provides exemplified second-nick gRNA species for optional use for correcting the pathogenic R243Q mutation in PAH. The gRNA spacers from Table 1C were filtered, e.g., filtered by occurrence within 15 nt of the desired editing location and use of a Tier 1 Cas enzyme. Second-nick gRNAs were generated by searching the opposite strand of DNA in the regions -40 to -140 (“left”) and +40 to +140 (“right”), relative to the first nick site defined by the first gRNA, for the PAM utilized by the corresponding Cas variant. One exemplary spacer is shown for each side of the target nick site.

ID	Left gRNA spacer	SEQ ID NO	Left PAM	Right gRNA spacer	SEQ ID NO	Right PAM

Table 2D: Exemplary left gRNA spacer and right gRNA spacer pairs

Table 2D provides exemplified second-nick gRNA species for optional use for correcting the pathogenic IVS10-11G>A mutation in PAH. The gRNA spacers from Table 1D were filtered, e.g., filtered by occurrence within 15 nt of the desired editing location and use of a Tier 1 Cas enzyme. Second-nick gRNAs were generated by searching the opposite strand of DNA in the regions -40 to -140 (“left”) and +40 to +140 (“right”), relative to the first nick site defined by the first gRNA, for the PAM utilized by the corresponding Cas variant. One exemplary spacer is shown for each side of the target nick site.

Capital letters indicate “core nucleotides” while lower case letters indicate “flanking nucleotides.” Herein, when an RNA sequence (e.g., a gRNA to produce a second nick) is said to comprise a particular sequence (e.g., a sequence of Table 2A, Table 2B, Table 2C, or Table 2D or a portion thereof) that comprises thymine (T), it is of course understood that the RNA sequence may (and frequently does) comprise uracil (U) in place of T. For instance, the RNA sequence may comprise U at every position shown as T in the sequence in Table 2A, Table 2B, Table 2C, or Table 2D. More specifically, the present disclosure provides an RNA sequence according to every gRNA spacer sequence shown in Table 2A, Table 2B, Table 2C, or Table 2D, wherein the RNA sequence has a U in place of each T in the sequence in Table 2A, Table 2B, Table 2C, or Table 2D.

In some embodiments, the systems and methods provided herein may comprise a template sequence listed in **Table** 4A, Table 4B, Table 4C, or Table 4D. Table 4A, Table 4B, Table 4C, or Table 4D provides exemplary template RNA sequences (column 4) and optional second-nick gRNA spacer sequences (column 5) designed to be paired with a gene modifying polypeptide to correct a mutation in the PAH gene. The templates in Table 4A, Table 4B, Table 4C, or Table 4D are meant to exemplify the total sequence of: (1) gRNA spacer (e.g., for targeting for first strand nick), (2) gRNA scaffold, (3) heterologous object sequence, and (4) PBS sequence (e.g., for initiating TPRT at first strand nick).

Table 4A. Exemplary template RNA sequences and second nick gRNA spacer sequences

Table 4A provides design of RNA components of gene modifying systems for correcting the pathogenic R408W, mutation in PAH. The gRNA spacers from Table 1A were filtered, e.g., filtered by occurrence within 15 nt of the desired editing location and use of a Tier 1 Cas enzyme. For each gRNA ID, this table details the sequence of a complete template RNA, optional second-nick gRNA, and Cas variant for use in a Cas-RT fusion gene modifying polypeptide. For exemplification, PBS sequences and post-edit homology regions (after the location of the edit) are set to 12 nt and 30 nt, respectively. Additionally, a second-nick gRNA is selected with preference for a distance near 100 nt from the first nick and a first preference for a design resulting in a PAM-in system, as described elsewhere in this application.

Table 4B. Exemplary template RNA sequences and second nick gRNA spacer sequences

Table 4B provides design of RNA components of gene modifying systems for correcting the pathogenic R261Q, mutation in PAH. The gRNA spacers from Table 1B were filtered, e.g., filtered by occurrence within 15 nt of the desired editing location and use of a Tier 1 Cas enzyme. For

each gRNA ID, this table details the sequence of a complete template RNA, optional second-nick gRNA, and Cas variant for use in a Cas-RT fusion gene modifying polypeptide. For exemplification, PBS sequences and post-edit homology regions (after the location of the edit) are set to 12 nt and 30 nt, respectively. Additionally, a second-nick gRNA is selected with preference for a distance near 100 nt from the first nick and a first preference for a design resulting in a PAM-in system, as described elsewhere in this application.

Table 4C. Exemplary template RNA sequences and second nick gRNA spacer sequences

Table 4C provides design of RNA components of gene modifying systems for correcting the pathogenic R243Q, mutation in PAH. The gRNA spacers from Table 1C were filtered, e.g., filtered by occurrence within 15 nt of the desired editing location and use of a Tier 1 Cas enzyme. For each gRNA ID, this table details the sequence of a complete template RNA, optional second-nick gRNA, and Cas variant for use in a Cas-RT fusion gene modifying polypeptide. For exemplification, PBS sequences and post-edit homology regions (after the location of the edit) are set to 12 nt and 30 nt, respectively. Additionally, a second-nick gRNA is selected with preference for a distance near 100 nt from the first nick and a first preference for a design resulting in a PAM-in system, as described elsewhere in this application.

ID	Cas species	strand	Template RNA	SEQ ID NO	second-nick gRNA	SEQ ID NO

Table 4D. Exemplary template RNA sequences and second nick gRNA spacer sequences

Table 4D provides design of RNA components of gene modifying systems for correcting the pathogenic IVS10-11G>A, mutation in PAH. The gRNA spacers from Table 1D were filtered, e.g., filtered by occurrence within 15 nt of the desired editing location and use of a Tier 1 Cas enzyme. For each gRNA ID, this table details the sequence of a complete template RNA, optional second-nick gRNA, and Cas variant for use in a Cas-RT fusion gene modifying polypeptide. For exemplification, PBS sequences and post-edit homology regions (after the location of the edit) are set to 12 nt and 30 nt, respectively. Additionally, a second-nick gRNA is selected with preference for a distance near 100 nt from the first nick and a first preference for a design resulting in a PAM-in system, as described elsewhere in this application.

Capital letters indicate "core nucleotides" while lower case letters indicate "flanking nucleotides." Herein, when an RNA sequence (e.g., a template RNA sequence) is said to comprise a particular sequence (e.g., a sequence of Table 4A, Table 4B, Table 4C, or Table 4D or a portion thereof) that comprises thymine (T), it is of course understood that the RNA sequence may (and frequently does) comprise uracil (U) in place of T. For instance, the RNA sequence may comprise U at every position shown as T in the sequence in Table 4A, Table 4B, Table 4C, or Table 4D. More specifically, the present disclosure provides an RNA sequence

according to every template sequence shown in Table 4A, Table 4B, Table 4C, or Table 4D, wherein the RNA sequence has a U in place of each T in the sequence of Table 4A, Table 4B, Table 4C, or Table 4D.

In some embodiments, the systems and methods provided herein may comprise a template sequence listed in any of **Tables 5A-5F**. Tables 5A-5F provide exemplary template RNA sequences (column 2) designed to be paired with a gene modifying polypeptide to correct a mutation in the PAH gene. The templates in Tables 5A-5F are meant to exemplify the total sequence of: (1) gRNA spacer (e.g., for targeting for first strand nick), (2) gRNA scaffold, (3) RT (heterologous object sequence) sequence, and (4) PBS sequence (e.g., for initiating TPRT at first strand nick).

Table 5A. Exemplary template RNA sequences

Table 5A provides design of exemplary DNA components of gene modifying systems for correcting the pathogenic R408W mutation in PAH to the wild-type form. This table details the sequence of a complete template RNA for use in exemplary gene modifying systems comprising a gene modifying polypeptide. Templates in this table employ the hPKU1 spacer (ACCTCAATCCTTTGGGTGTA SEQ ID NO: 16355).

Table 5B. Exemplary template RNA sequences

Table 5B provides design of exemplary DNA components of gene modifying systems for correcting the pathogenic R408W mutation in PAH to the wild-type form. This table details the sequence of a complete template RNA for use in exemplary gene modifying systems comprising a gene modifying polypeptide. Templates in this table employ the hPKU2 spacer CCTCAATCCTTTGGGTGTAT (SEQ ID NO: 16332).

Table 5C. Exemplary template RNA sequences

Table 5C provides design of exemplary DNA components of gene modifying systems for correcting the pathogenic R408W mutation in PAH to the wild-type form. This table details the sequence of a complete template RNA for use in exemplary gene modifying systems comprising a gene modifying polypeptide. Templates in this table employ the hPKU33 spacer TGGGTCGTAGCGAACTGAGA (SEQ ID NO: 16102).

Table 5D. Exemplary template RNA sequences

Table 5D provides design of exemplary DNA components of gene modifying systems for correcting the pathogenic R408W mutation in PAH to the wild-type form. This table details the sequence of a complete template RNA for use in exemplary gene modifying systems comprising a gene modifying polypeptide. Templates in this table employ the hPKU4 spacer GGGTCGTAGCGAACTGAGAA (SEQ ID NO:16084).

Table 5E. Exemplary template RNA sequences

Table 5E provides design of exemplary DNA components of gene modifying systems for correcting the pathogenic R408W mutation in PAH to the wild-type form. This table details the sequence of a complete template RNA for use in exemplary gene modifying systems comprising a gene modifying polypeptide. Templates in this table employ the hPKU5 spacer TAGCGAACTGAGAAGGGCCA (SEQ ID NO: 16011).

Table 5F. Exemplary template RNA sequences

Table 5F provides design of exemplary DNA components of gene modifying systems for correcting the pathogenic R408W mutation in PAH to the wild-type form. This table details the sequence of a complete template RNA for use in exemplary gene modifying systems comprising a gene modifying polypeptide. Templates in this table employ the hPKU6 spacer ACTTTGCTGCCACAATACCT (SEQ ID NO: 16032).

In some embodiments, the systems and methods provided herein may comprise a template sequence listed in **Table 6A**. Table 6A provides exemplary template RNA sequences (column 4) and second-nick gRNA spacer sequences (column 3) designed to be paired with a gene modifying polypeptide to correct a R408W mutation in the PAH gene.

Table 6A. Exemplary second nick gRNA sequences

Table 6A provides spacer sequences for second-strand targeting gRNAs and relevant characteristics. Second-nick gRNAs in this table are designed to be used in combination with template RNAs comprising the particular spacers noted in Column 6. In some embodiments, a second-nick gRNA is selected with preference for a distance of less than or equal to 100 nt from the first nick (i.e., the nick specified by the template RNA). In some embodiments, a second-nick gRNA is selected with a preference for a PAM-in orientation with the template RNA of the gene modifying system, as described elsewhere in this application.

The template RNA sequences shown in Tables 1-4, 5A-5F, and 6A may be customized depending on the cell being targeted. For example, in some embodiments it is desired to inactivate a PAM sequence upon editing (e.g., using a "PAM-kill" modification) to decrease the potential for further gene editing (e.g., by Cas retargeting) following the initial edit. Consequently, certain template RNAs described herein are designed to write a mutation (e.g., a substitution) into the PAM of the target site, such that upon editing, the PAM site will be mutated to a sequence no longer recognized by the gene modifying polypeptide. Thus, a mutation region within the heterologous object sequence of the template RNA may comprise a PAM-kill sequence. Without wishing to be bound by theory, in some embodiments, a PAM-kill sequence prevents re-engagement of the gene modifying polypeptide upon completion of a genetic modification, or decreases re-engagement relative to a template RNA lacking a PAM-kill sequence. In some embodiments, a PAM-kill sequence does not alter the amino acid sequence encoded by a gene, e.g., the PAM-kill sequence results in a silent mutation. In other embodiments, it is desired to leave the PAM sequence intact (no PAM-kill).

Similarly, in some embodiments, to decrease the potential for further gene editing (e.g., by Cas retargeting) following the initial edit, it may be desirable to alter the first three nucleotides of the RT template sequence via a "seed-kill" motif. Consequently, certain template RNAs described herein are designed to write a mutation (e.g., a substitution) into the portion of the target site corresponding to the first three nucleotides of the RT template sequence, such that upon editing, the target site will be mutated to a sequence with lower homology to the RT template sequence. Thus, a mutation region within the heterologous object sequence of the template RNA may comprise a seed-kill sequence. Without wishing to be bound by theory, in some embodiments, a seed-kill sequence prevents re-engagement of the gene modifying polypeptide upon completion of a genetic modification, or decreases re-engagement relative to an otherwise similar template RNA lacking a seed-kill sequence. In some embodiments, a seed-kill sequence does not alter the amino acid sequence encoded by a gene, e.g., the seed-kill sequence results in a silent mutation. In other embodiments, it is desired to leave the seed region intact, and a seed-kill sequence is not used.

In further embodiments, to optimize or improve gene editing efficiency, it may be desirable to evade the target cell's mismatch repair or nucleotide repair pathways or to bias the

target cell's repair pathways toward preservation of the edited strand. In some embodiments, multiple silent mutations (for example, silent substitutions) may be introduced within the RT template sequence to evade the target cell's mismatch repair or nucleotide repair pathways or to bias the target cell's repair pathways toward preservation of the edited strand.

Table 7A provides exemplary silent mutations for various positions within the PAH gene for use with a template to correct a R408W mutation.

In some embodiments, the template RNA comprises one or more silent mutations.

It should be understood that the silent mutations illustrated in Tables 7A-7C may be used individually or combined in any manner in a template RNA sequence described herein.
In some embodiments, the template RNA comprises a sequence having one or more silent substitutions as shown in Table E6 or E6A.

In some embodiments, the template RNA comprises a sequence listed in any one of Tables 8A-8D. Tables 8A-8D provide exemplary template RNA sequences comprising one or more silent substitutions (column 2) designed to be paired with a gene modifying polypeptide to correct a mutation in the PAH gene. The templates in Tables 5A-5F are meant to exemplify the total sequence of: (1) gRNA spacer (e.g., for targeting for first strand nick), (2) gRNA scaffold, (3) RT (heterologous object sequence) sequence, and (4) PBS sequence (e.g., for initiating TPRT at first strand nick).

Table 8A. Exemplary template RNA sequences

Table 8A provides design of exemplary components of gene modifying systems for correcting the pathogenic R408W mutation in PAH to the wild-type form. This table details the sequence of a complete template RNA comprising one or more silent substitutions described in Table 7A for use in a Cas-RT fusion gene modifying polypeptide. Templates in this table employ the hPKU3 spacer TGGGTCGTAGCGAACTGAGA (SEQ ID NO: 16102).

Table 8B. Exemplary template RNA sequences

Table 8B provides design of exemplary DNA components of gene modifying systems for correcting the pathogenic R408W mutation in PAH to the wild-type form. This table details the sequence of a complete template RNA comprising one or more silent substitutions described in Table 7A for use in a Cas-RT fusion gene modifying polypeptide. Templates in this table employ the hPKU4 spacer GGGTCGTAGCGAACTGAGAA (SEQ ID NO:16084).

Table 8C. Exemplary template RNA sequences

Table 8C provides design of exemplary DNA components of gene modifying systems for correcting the pathogenic R408W mutation in PAH to the wild-type form. This table details the sequence of a complete template RNA comprising one or more silent substitutions described in Table 7A for use in a Cas-RT fusion gene modifying polypeptide. Templates in this table employ the hPKU5 spacer TAGCGAACTGAGAAGGGCCA (SEQ ID NO: 16011).

Table 8D. Exemplary template RNA sequences

Table 8D provides design of exemplary DNA components of gene modifying systems for correcting the pathogenic R408W mutation in PAH to the wild-type form. This table details the sequence of a complete template RNA comprising one or more silent substitutions described in Table 7A for use in a Cas-RT fusion gene modifying polypeptide. Templates in this table employ the hPKU6 spacer ACTTTGCTGCCACAATACCT (SEQ ID NO: 16032).

gRNAs with inducible activity

In some embodiments, a gRNA described herein (e.g., a gRNA that is part of a template RNA or a gRNA used for second strand nicking) has inducible activity. Inducible activity may be achieved by the template nucleic acid, e.g., template RNA, further comprising (in addition to the gRNA) a blocking domain, wherein the sequence of a portion of or all of the blocking domain is at least partially complementary to a portion or all of the gRNA. The blocking domain is thus capable of hybridizing or substantially hybridizing to a portion of or all of the gRNA. In some embodiments, the blocking domain and inducibly active gRNA are disposed on the template nucleic acid, e.g., template RNA, such that the gRNA can adopt a first conformation where the blocking domain is hybridized or substantially hybridized to the gRNA, and a second conformation where the blocking domain is not hybridized or not substantially hybridized to the gRNA. In some embodiments, in the first conformation the gRNA is unable to bind to the gene modifying polypeptide (e.g., the template nucleic acid binding domain, DNA binding domain, or endonuclease domain (e.g., a CRISPR/Cas protein)) or binds with substantially decreased affinity compared to an otherwise similar template RNA lacking the blocking domain. In some embodiments, in the second conformation the gRNA is able to bind to the gene modifying polypeptide (e.g., the template nucleic acid binding domain, DNA binding domain, or endonuclease domain (e.g., a CRISPR/Cas protein)). In some embodiments, whether the gRNA is in the first or second conformation can influence whether the DNA binding or endonuclease activities of the gene modifying polypeptide (e.g., of the CRISPR/Cas protein the gene modifying polypeptide comprises) are active.

In some embodiments, the gRNA that coordinates the second nick has inducible activity. In some embodiments, the gRNA that coordinates the second nick is induced after the template is reverse transcribed. In some embodiments, hybridization of the gRNA to the blocking domain can be disrupted using an opener molecule. In some embodiments, an opener molecule comprises an agent that binds to a portion or all of the gRNA or blocking domain and inhibits hybridization of the gRNA to the blocking domain. In some embodiments, the opener molecule comprises a nucleic acid, e.g., comprising a sequence that is partially or wholly complementary to the gRNA, blocking domain, or both. By choosing or designing an appropriate opener molecule, providing the opener molecule can promote a change in the conformation of the gRNA such that it can associate with a CRISPR/Cas protein and provide the associated functions of the

CRISPR/Cas protein (e.g., DNA binding and/or endonuclease activity). Without wishing to be bound by theory, providing the opener molecule at a selected time and/or location may allow for spatial and temporal control of the activity of the gRNA, CRISPR/Cas protein, or gene modifying system comprising the same. In some embodiments, the opener molecule is exogenous to the cell comprising the gene modifying polypeptide and or template nucleic acid. In some embodiments, the opener molecule comprises an endogenous agent (e.g., endogenous to the cell comprising the gene modifying polypeptide and or template nucleic acid comprising the gRNA and blocking domain). For example, an inducible gRNA, blocking domain, and opener molecule may be chosen such that the opener molecule is an endogenous agent expressed in a target cell or tissue, e.g., thereby ensuring activity of a gene modifying system in the target cell or tissue. As a further example, an inducible gRNA, blocking domain, and opener molecule may be chosen such that the opener molecule is absent or not substantially expressed in one or more non-target cells or tissues, e.g., thereby ensuring that activity of a gene modifying system does not occur or substantially occur in the one or more non-target cells or tissues, or occurs at a reduced level compared to a target cell or tissue. Exemplary blocking domains, opener molecules, and uses thereof are described in PCT App. Publication WO2020044039A1, which is incorporated herein by reference in its entirety. In some embodiments, the template nucleic acid, e.g., template RNA, may comprise one or more sequences or structures for binding by one or more components of a gene modifying polypeptide, e.g., by a reverse transcriptase or RNA binding domain, and a gRNA. In some embodiments, the gRNA facilitates interaction with the template nucleic acid binding domain (e.g., RNA binding domain) of the gene modifying polypeptide. In some embodiments, the gRNA directs the gene modifying polypeptide to the matching target sequence, e.g., in a target cell genome.

Circular RNAs and Ribozymes in Gene Modifying Systems

It is contemplated that it may be useful to employ circular and/or linear RNA states during the formulation, delivery, or gene modifying reaction within the target cell. Thus, in some embodiments of any of the aspects described herein, a gene modifying system comprises one or more circular RNAs (circRNAs). In some embodiments of any of the aspects described herein, a gene modifying system comprises one or more linear RNAs. In some embodiments, a nucleic acid as described herein (e.g., a template nucleic acid, a nucleic acid molecule encoding a

gene modifying polypeptide, or both) is a circRNA. In some embodiments, a circular RNA molecule encodes the gene modifying polypeptide. In some embodiments, the circRNA molecule encoding the gene modifying polypeptide is delivered to a host cell. In some embodiments, a circular RNA molecule encodes a recombinase, e.g., as described herein. In some embodiments, the circRNA molecule encoding the recombinase is delivered to a host cell. In some embodiments, the circRNA molecule encoding the gene modifying polypeptide is linearized (e.g., in the host cell, e.g., in the nucleus of the host cell) prior to translation.

Circular RNAs (circRNAs) have been found to occur naturally in cells and have been found to have diverse functions, including both non-coding and protein coding roles in human cells. It has been shown that a circRNA can be engineered by incorporating a self-splicing intron into an RNA molecule (or DNA encoding the RNA molecule) that results in circularization of the RNA, and that an engineered circRNA can have enhanced protein production and stability (Wesselhoeft et al. *Nature Communications* 2018). In some embodiments, the gene modifying polypeptide is encoded as circRNA. In certain embodiments, the template nucleic acid is a DNA, such as a dsDNA or ssDNA. In certain embodiments, the circDNA comprises a template RNA.

In some embodiments, the circRNA comprises one or more ribozyme sequences. In some embodiments, the ribozyme sequence is activated for autocleavage, e.g., in a host cell, e.g., thereby resulting in linearization of the circRNA. In some embodiments, the ribozyme is activated when the concentration of magnesium reaches a sufficient level for cleavage, e.g., in a host cell. In some embodiments the circRNA is maintained in a low magnesium environment prior to delivery to the host cell. In some embodiments, the ribozyme is a protein-responsive ribozyme. In some embodiments, the ribozyme is a nucleic acid-responsive ribozyme. In some embodiments, the circRNA comprises a cleavage site. In some embodiments, the circRNA comprises a second cleavage site.

In some embodiments, the circRNA is linearized in the nucleus of a target cell. In some embodiments, linearization of a circRNA in the nucleus of a cell involves components present in the nucleus of the cell, e.g., to activate a cleavage event. In some embodiments, a ribozyme, e.g., a ribozyme from a B2 or ALU element, that is responsive to a nuclear element, e.g., a nuclear protein, e.g., a genome-interacting protein, e.g., an epigenetic modifier, e.g., EZH2, is

incorporated into a circRNA, e.g., of a gene modifying system. In some embodiments, nuclear localization of the circRNA results in an increase in autocatalytic activity of the ribozyme and linearization of the circRNA.

In some embodiments, the ribozyme is heterologous to one or more of the other components of the gene modifying system. In some embodiments, an inducible ribozyme (e.g., in a circRNA as described herein) is created synthetically, for example, by utilizing a protein ligand-responsive aptamer design. A system for utilizing the satellite RNA of tobacco ringspot virus hammerhead ribozyme with an MS2 coat protein aptamer has been described (Kennedy et al. Nucleic Acids Res 42(19):12306-12321 (2014), incorporated herein by reference in its entirety) that results in activation of the ribozyme activity in the presence of the MS2 coat protein. In embodiments, such a system responds to protein ligand localized to the cytoplasm or the nucleus. In some embodiments the protein ligand is not MS2. Methods for generating RNA aptamers to target ligands have been described, for example, based on the systematic evolution of ligands by exponential enrichment (SELEX) (Tuerk and Gold, Science 249(4968):505-510 (1990); Ellington and Szostak, Nature 346(6287):818-822 (1990); the methods of each of which are incorporated herein by reference) and have, in some instances, been aided by *in silico* design (Bell et al. PNAS 117(15):8486-8493, the methods of which are incorporated herein by reference). Thus, in some embodiments, an aptamer for a target ligand is generated and incorporated into a synthetic ribozyme system, e.g., to trigger ribozyme-mediated cleavage and circRNA linearization, e.g., in the presence of the protein ligand. In some embodiments, circRNA linearization is triggered in the cytoplasm, e.g., using an aptamer that associates with a ligand in the cytoplasm. In some embodiments, circRNA linearization is triggered in the nucleus, e.g., using an aptamer that associates with a ligand in the nucleus. In embodiments, the ligand in the nucleus comprises an epigenetic modifier or a transcription factor. In some embodiments the ligand that triggers linearization is present at higher levels in on-target cells than off-target cells.

It is further contemplated that a nucleic acid-responsive ribozyme system can be employed for circRNA linearization. For example, biosensors that sense defined target nucleic acid molecules to trigger ribozyme activation are described, e.g., in Penchovsky (Biotechnology Advances 32(5):1015-1027 (2014), incorporated herein by reference). By these methods, a ribozyme naturally folds into an inactive state and is only activated in the presence of a defined

target nucleic acid molecule (e.g., an RNA molecule). In some embodiments, a circRNA of a gene modifying system comprises a nucleic acid-responsive ribozyme that is activated in the presence of a defined target nucleic acid, e.g., an RNA, e.g., an mRNA, miRNA, guide RNA, gRNA, sgRNA, ncRNA, lncRNA, tRNA, snRNA, or mtRNA. In some embodiments the nucleic acid that triggers linearization is present at higher levels in on-target cells than off-target cells.

In some embodiments of any of the aspects herein, a gene modifying system incorporates one or more ribozymes with inducible specificity to a target tissue or target cell of interest, e.g., a ribozyme that is activated by a ligand or nucleic acid present at higher levels in a target tissue or target cell of interest. In some embodiments, the gene modifying system incorporates a ribozyme with inducible specificity to a subcellular compartment, e.g., the nucleus, nucleolus, cytoplasm, or mitochondria. In some embodiments, the ribozyme that is activated by a ligand or nucleic acid present at higher levels in the target subcellular compartment. In some embodiments, an RNA component of a gene modifying system is provided as circRNA, e.g., that is activated by linearization. In some embodiments, linearization of a circRNA encoding a gene modifying polypeptide activates the molecule for translation. In some embodiments, a signal that activates a circRNA component of a gene modifying system is present at higher levels in on-target cells or tissues, e.g., such that the system is specifically activated in these cells.

In some embodiments, an RNA component of a gene modifying system is provided as a circRNA that is inactivated by linearization. In some embodiments, a circRNA encoding the gene modifying polypeptide is inactivated by cleavage and degradation. In some embodiments, a circRNA encoding the gene modifying polypeptide is inactivated by cleavage that separates a translation signal from the coding sequence of the polypeptide. In some embodiments, a signal that inactivates a circRNA component of a gene modifying system is present at higher levels in off-target cells or tissues, such that the system is specifically inactivated in these cells.

Target Nucleic Acid Site

In some embodiments, after gene modification, the target site surrounding the edited sequence contains a limited number of insertions or deletions, for example, in less than about 50% or 10% of editing events, e.g., as determined by long-read amplicon sequencing of the target site, e.g., as described in Karst et al. (2020) *bioRxiv* doi.org/10.1101/645903 (incorporated by reference herein in its entirety). In some embodiments, the target site does not show multiple

consecutive editing events, e.g., head-to-tail or head-to-head duplications, e.g., as determined by long-read amplicon sequencing of the target site, e.g., as described in Karst et al. *bioRxiv* doi.org/10.1101/645903 (2020) (incorporated herein by reference in its entirety). In some embodiments, the target site contains an integrated sequence corresponding to the template RNA. In some embodiments, the target site does not contain insertions resulting from endogenous RNA in more than about 1% or 10% of events, e.g., as determined by long-read amplicon sequencing of the target site, e.g., as described in Karst et al. *bioRxiv* doi.org/10.1101/645903 (2020) (incorporated herein by reference in its entirety). In some embodiments, the target site contains the integrated sequence corresponding to the template RNA.

In certain aspects of the present invention, the host DNA-binding site integrated into by the gene modifying system can be in a gene, in an intron, in an exon, an ORF, outside of a coding region of any gene, in a regulatory region of a gene, or outside of a regulatory region of a gene. In other aspects, the polypeptide may bind to one or more than one host DNA sequence.

In some embodiments, a gene modifying system is used to edit a target locus in multiple alleles. In some embodiments, a gene modifying system is designed to edit a specific allele. For example, a gene modifying polypeptide may be directed to a specific sequence that is only present on one allele, e.g., comprises a template RNA with homology to a target allele, e.g., a gRNA or annealing domain, but not to a second cognate allele. In some embodiments, a gene modifying system can alter a haplotype-specific allele. In some embodiments, a gene modifying system that targets a specific allele preferentially targets that allele, e.g., has at least a 2, 4, 6, 8, or 10-fold preference for a target allele.

Second Strand Nicking

In some embodiments, a gene modifying system described herein comprises a nickase activity (e.g., in the gene modifying polypeptide) that nicks the first strand, and a nickase activity (e.g., in a polypeptide separate from the gene modifying polypeptide) that nicks the second strand of target DNA. As discussed herein, without wishing to be bound by theory, nicking of the first strand of the target site DNA is thought to provide a 3´ OH that can be used by an RT domain to reverse transcribe a sequence of a template RNA, e.g., a heterologous object sequence. Without wishing to be bound by theory, it is thought that introducing an additional nick to the second strand may bias the cellular DNA repair machinery to adopt the heterologous object

sequence-based sequence more frequently than the original genomic sequence. In some embodiments, the additional nick to the second strand is made by the same endonuclease domain (e.g., nickase domain) as the nick to the first strand. In some embodiments, the same gene modifying polypeptide performs both the nick to the first strand and the nick to the second strand. In some embodiments, the gene modifying polypeptide comprises a CRISPR/Cas domain and the additional nick to the second strand is directed by an additional nucleic acid, e.g., comprising a second gRNA directing the CRISPR/Cas domain to nick the second strand. In other embodiments, the additional second strand nick is made by a different endonuclease domain (e.g., nickase domain) than the nick to the first strand. In some embodiments, that different endonuclease domain is situated in an additional polypeptide (e.g., a system of the invention further comprises the additional polypeptide), separate from the gene modifying polypeptide. In some embodiments, the additional polypeptide comprises an endonuclease domain (e.g., nickase domain) described herein. In some embodiments, the additional polypeptide comprises a DNA binding domain, e.g., described herein.

It is contemplated herein that the position at which the second strand nick occurs relative to the first strand nick may influence the extent to which one or more of: desired gene modifying DNA modifications are obtained, undesired double-strand breaks (DSBs) occur, undesired insertions occur, or undesired deletions occur. Without wishing to be bound by theory, second strand nicking may occur in two general orientations: inward nicks and outward nicks.

In some embodiments, in the inward nick orientation, the RT domain polymerizes (e.g., using the template RNA (e.g., the heterologous object sequence)) away from the second strand nick. In some embodiments, in the inward nick orientation, the location of the nick to the first strand and the location of the nick to the second strand are positioned between the first PAM site and second PAM site (e.g., in a scenario wherein both nicks are made by a polypeptide (e.g., a gene modifying polypeptide) comprising a CRISPR/Cas domain). When there are two PAMs on the outside and two nicks on the inside, this inward nick orientation can also be referred to as "PAM-out". In some embodiments, in the inward nick orientation, the location of the nick to the first strand and the location of the nick to the second strand are between the sites where the polypeptide and the additional polypeptide bind to the target DNA. In some embodiments, in the inward nick orientation, the location of the nick to the second strand is positioned between the binding sites of the polypeptide and additional polypeptide, and the nick to the first strand is also

located between the binding sites of the polypeptide and additional polypeptide. In some embodiments, in the inward nick orientation, the location of the nick to the first strand and the location of the nick to the second strand are positioned between the PAM site and the binding site of the second polypeptide which is at a distance from the target site.

An example of a gene modifying system that provides an inward nick orientation comprises a gene modifying polypeptide comprising a CRISPR/Cas domain, a template RNA comprising a gRNA that directs nicking of the target site DNA on the first strand, and an additional nucleic acid comprising an additional gRNA that directs nicking at a site a distance from the location of the first nick, wherein the location of the first nick and the location of the second nick are between the PAM sites of the sites to which the two gRNAs direct the gene modifying polypeptide. As a further example, another gene modifying system that provides an inward nick orientation comprises a gene modifying polypeptide comprising a zinc finger molecule and a first nickase domain wherein the zinc finger molecule binds to the target DNA in a manner that directs the first nickase domain to nick the first strand of the target site; an additional polypeptide comprising a CRISPR/Cas domain, and an additional nucleic acid comprising a gRNA that directs the additional polypeptide to nick a site a distance from the target site DNA on the second strand, wherein the location of the first nick and the location of the second nick are between the PAM site and the site to which the zinc finger molecule binds. As a further example, another gene modifying system that provides an inward nick orientation comprises a gene modifying polypeptide comprising a zinc finger molecule and a first nickase domain wherein the zinc finger molecule binds to the target DNA in a manner that directs the first nickase domain to nick the first strand of the target site; an additional polypeptide comprising a TAL effector molecule and a second nickase domain wherein the TAL effector molecule binds to a site a distance from the target site in a manner that directs the additional polypeptide to nick the second strand, wherein the location of the first nick and the location of the second nick are between the site to which the TAL effector molecule binds and the site to which the zinc finger molecule binds.

In some embodiments, in the outward nick orientation, the RT domain polymerizes (e.g., using the template RNA (e.g., the heterologous object sequence)) toward the second strand nick. In some embodiments, in the outward nick orientation when both the first and second nicks are made by a polypeptide comprising a CRISPR/Cas domain (e.g., a gene modifying

polypeptide), the first PAM site and second PAM site are positioned between the location of the nick to the first strand and the location of the nick to the second strand. When there are two PAMs on the inside and two nicks on the outside, this outward nick orientation also can be referred to as "PAM-in". In some embodiments, in the outward nick orientation, the polypeptide (e.g., the gene modifying polypeptide) and the additional polypeptide bind to sites on the target DNA between the location of the nick to the first strand and the location of the nick to the second. In some embodiments, in the outward nick orientation, the location of the nick to the second strand is positioned on the opposite side of the binding sites of the polypeptide and additional polypeptide relative to the location of the nick to the first strand. In some embodiments, in the outward orientation, the PAM site and the binding site of the second polypeptide which is at a distance from the target site are positioned between the location of the nick to the first strand and the location of the nick to the second strand.

An example of a gene modifying system that provides an outward nick orientation comprises a gene modifying polypeptide comprising a CRISPR/Cas domain, a template RNA comprising a gRNA that directs nicking of the target site DNA on the first strand, and an additional nucleic acid comprising an additional gRNA that directs nicking at a site a distance from the location of the first nick, wherein the location of the first nick and the location of the second nick are outside of the PAM sites of the sites to which the two gRNAs direct the gene modifying polypeptide (i.e., the PAM sites are between the location of the first nick and the location of the second nick). As a further example, another gene modifying system that provides an outward nick orientation comprises a gene modifying polypeptide comprising a zinc finger molecule and a first nickase domain wherein the zinc finger molecule binds to the target DNA in a manner that directs the first nickase domain to nick the first strand of the target site; an additional polypeptide comprising a CRISPR/Cas domain, and an additional nucleic acid comprising a gRNA that directs the additional polypeptide to nick a site a distance from the target site DNA on the second strand, wherein the location of the first nick and the location of the second nick are outside the PAM site and the site to which the zinc finger molecule binds (i.e., the PAM site and the site to which the zinc finger molecule binds are between the location of the first nick and the location of the second nick). As a further example, another gene modifying system that provides an outward nick orientation comprises a gene modifying polypeptide comprising a zinc finger molecule and a first nickase domain wherein the zinc finger

molecule binds to the target DNA in a manner that directs the first nickase domain to nick the first strand of the target site; an additional polypeptide comprising a TAL effector molecule and a second nickase domain wherein the TAL effector molecule binds to a site a distance from the target site in a manner that directs the additional polypeptide to nick the second strand, wherein the location of the first nick and the location of the second nick are outside the site to which the TAL effector molecule binds and the site to which the zinc finger molecule binds (i.e., the site to which the TAL effector molecule binds and the site to which the zinc finger molecule binds are between the location of the first nick and the location of the second nick).

Without wishing to be bound by theory, it is thought that, for gene modifying systems where a second strand nick is provided, an outward nick orientation is preferred in some embodiments. As is described herein, an inward nick may produce a higher number of double-strand breaks (DSBs) than an outward nick orientation. DSBs may be recognized by the DSB repair pathways in the nucleus of a cell, which can result in undesired insertions and deletions. An outward nick orientation may provide a decreased risk of DSB formation, and a corresponding lower amount of undesired insertions and deletions. In some embodiments, undesired insertions and deletions are insertions and deletions not encoded by the heterologous object sequence, e.g., an insertion or deletion produced by the double-strand break repair pathway unrelated to the modification encoded by the heterologous object sequence. In some embodiments, a desired gene modification comprises a change to the target DNA (e.g., a substitution, insertion, or deletion) encoded by the heterologous object sequence (e.g., and achieved by the gene modifying writing the heterologous object sequence into the target site). In some embodiments, the first strand nick and the second strand nick are in an outward orientation.

In addition, the distance between the first strand nick and second strand nick may influence the extent to which one or more of: desired gene modifying system DNA modifications are obtained, undesired double-strand breaks (DSBs) occur, undesired insertions occur, or undesired deletions occur. Without wishing to be bound by theory, it is thought the second strand nick benefit, the biasing of DNA repair toward incorporation of the heterologous object sequence into the target DNA, increases as the distance between the first strand nick and second strand nick decreases. However, it is thought that the risk of DSB formation also increases as the distance between the first strand nick and second strand nick decreases. Correspondingly, it is thought that the number of undesired insertions and/or deletions may increase as the distance

between the first strand nick and second strand nick decreases. In some embodiments, the distance between the first strand nick and second strand nick is chosen to balance the benefit of biasing DNA repair toward incorporation of the heterologous object sequence into the target DNA and the risk of DSB formation and of undesired deletions and/or insertions. In some embodiments, a system where the first strand nick and the second strand nick are at least a threshold distance apart has an increased level of desired gene modifying system modification outcomes, a decreased level of undesired deletions, and/or a decreased level of undesired insertions relative to an otherwise similar inward nick orientation system where the first nick and the second nick are less than the a threshold distance apart. In some embodiments the threshold distance(s) is given below.

In some embodiments, the first nick and the second nick are at least 20, 25, 30, 35, 40, 45, 50, 55, 60, 65, 70, 75, 80, 85, 90, 95, 100, 110, 120, 130, 140, 150, 160, 170, 180, 190, or 200 nucleotides apart. In some embodiments, the first nick and the second nick are no more than 25, 30, 35, 40, 45, 50, 55, 60, 65, 70, 75, 80, 85, 90, 95, 100, 110, 120, 130, 140, 150, 160, 170, 180, 190, 200, or 250 nucleotides apart. In some embodiments, the first nick and the second nick are 20-200, 30-200, 40-200, 50-200, 60-200, 70-200, 80-200, 90-200, 100-200, 110-200, 120-200, 130-200, 140-200, 150-200, 160-200, 170-200, 180-200, 190-200, 20-190, 30-190, 40-190, 50-190, 60-190, 70-190, 80-190, 90-190, 100-190, 110-190, 120-190, 130-190, 140-190, 150-190, 160-190, 170-190, 180-190, 20-180, 30-180, 40-180, 50-180, 60-180, 70-180, 80-180, 90-180, 100-180, 110-180, 120-180, 130-180, 140-180, 150-180, 160-180, 170-180, 20-170, 30-170, 40-170, 50-170, 60-170, 70-170, 80-170, 90-170, 100-170, 110-170, 120-170, 130-170, 140-170, 150-170, 160-170, 20-160, 30-160, 40-160, 50-160, 60-160, 70-160, 80-160, 90-160, 100-160, 110-160, 120-160, 130-160, 140-160, 150-160, 20-150, 30-150, 40-150, 50-150, 60-150, 70-150, 80-150, 90-150, 100-150, 110-150, 120-150, 130-150, 140-150, 20-140, 30-140, 40-140, 50-140, 60-140, 70-140, 80-140, 90-140, 100-140, 110-140, 120-140, 130-140, 20-130, 30-130, 40-130, 50-130, 60-130, 70-130, 80-130, 90-130, 100-130, 110-130, 120-130, 20-120, 30-120, 40-120, 50-120, 60-120, 70-120, 80-120, 90-120, 100-120, 110-120, 20-110, 30-110, 40-110, 50-110, 60-110, 70-110, 80-110, 90-110, 100-110, 20-100, 30-100, 40-100, 50-100, 60-100, 70-100, 80-100, 90-100, 20-90, 30-90, 40-90, 50-90, 60-90, 70-90, 80-90, 20-80, 30-80, 40-80, 50-80, 60-80, 70-80, 20-70, 30-70, 40-70, 50-70, 60-70, 20-60, 30-60, 40-60, 50-60, 20-50, 30-

50, 40-50, 20-40, 30-40, or 20-30 nucleotides apart. In some embodiments, the first nick and the second nick are 40-100 nucleotides apart.

Without wishing to be bound by theory, it is thought that, for gene modifying systems where a second strand nick is provided and an inward nick orientation is selected, increasing the distance between the first strand nick and second strand nick may be preferred. As is described herein, an inward nick orientation may produce a higher number of DSBs than an outward nick orientation, and may result in a higher amount of undesired insertions and deletions than an outward nick orientation, but increasing the distance between the nicks may mitigate that increase in DSBs, undesired deletions, and/or undesired insertions. In some embodiments, an inward nick orientation wherein the first nick and the second nick are at least a threshold distance apart has an increased level of desired gene modifying system modification outcomes, a decreased level of undesired deletions, and/or a decreased level of undesired insertions relative to an otherwise similar inward nick orientation system where the first nick and the second nick are less than the a threshold distance apart. In some embodiments the threshold distance is given below.

In some embodiments, the first strand nick and the second strand nick are in an inward orientation. In some embodiments, the first strand nick and the second strand nick are in an inward orientation and the first strand nick and second strand nick are at least 100, 110, 120, 130, 140, 150, 160, 170, 180, 190, 200, 220, 240, 260, 280, 300, 350, 400, 450, or 500 nucleotides apart, e.g., at least 100 nucleotides apart, (and optionally no more than 500, 400, 300, 200, 190, 180, 170, 160, 150, 140, 130, or 120 nucleotides apart). In some embodiments, the first strand nick and the second strand nick are in an inward orientation and the first strand nick and second strand nick are 100-200, 110-200, 120-200, 130-200, 140-200, 150-200, 160-200, 170-200, 180-200, 190-200, 100-190, 110-190, 120-190, 130-190, 140-190, 150-190, 160-190, 170-190, 180-190, 100-180, 110-180, 120-180, 130-180, 140-180, 150-180, 160-180, 170-180, 100-170, 110-170, 120-170, 130-170, 140-170, 150-170, 160-170, 100-160, 110-160, 120-160, 130-160, 140-160, 150-160, 100-150, 110-150, 120-150, 130-150, 140-150, 100-140, 110-140, 120-140, 130-140, 100-130, 110-130, 120-130, 100-120, 110-120, or 100-110 nucleotides apart.

Chemically modified nucleic acids and nucleic acid end features

A nucleic acid described herein (e.g., a template nucleic acid, e.g., a template RNA; or a nucleic acid (e.g., mRNA) encoding a gene modifying polypeptide; or a gRNA) can comprise

unmodified or modified nucleobases. Naturally occurring RNAs are synthesized from four basic ribonucleotides: ATP, CTP, UTP and GTP, but may contain post-transcriptionally modified nucleotides. Further, approximately one hundred different nucleoside modifications have been identified in RNA (Rozenski, J, Crain, P, and McCloskey, J. (1999). The RNA Modification Database: 1999 update. Nucl Acids Res 27: 196-197). An RNA can also comprise wholly synthetic nucleotides that do not occur in nature.

In some embodiments, the chemical modification is one provided in WO/2016/183482, US Pat. Pub. No. 20090286852, of International Application No. WO/2012/019168, WO/2012/045075, WO/2012/135805, WO/2012/158736, WO/2013/039857, WO/2013/039861, WO/2013/052523, WO/2013/090648, WO/2013/096709, WO/2013/101690, WO/2013/106496, WO/2013/130161, WO/2013/151669, WO/2013/151736, WO/2013/151672, WO/2013/151664, WO/2013/151665, WO/2013/151668, WO/2013/151671, WO/2013/151667, WO/2013/151670, WO/2013/151666, WO/2013/151663, WO/2014/028429, WO/2014/081507, WO/2014/093924, WO/2014/093574, WO/2014/113089, WO/2014/144711, WO/2014/144767, WO/2014/144039, WO/2014/152540, WO/2014/152030, WO/2014/152031, WO/2014/152027, WO/2014/152211, WO/2014/158795, WO/2014/159813, WO/2014/164253, WO/2015/006747, WO/2015/034928, WO/2015/034925, WO/2015/038892, WO/2015/048744, WO/2015/051214, WO/2015/051173, WO/2015/051169, WO/2015/058069, WO/2015/085318, WO/2015/089511, WO/2015/105926, WO/2015/164674, WO/2015/196130, WO/2015/196128, WO/2015/196118, WO/2016/011226, WO/2016/011222, WO/2016/011306, WO/2016/014846, WO/2016/022914, WO/2016/036902, WO/2016/077125, or WO/2016/077123, each of which is herein incorporated by reference in its entirety. It is understood that incorporation of a chemically modified nucleotide into a polynucleotide can result in the modification being incorporated into a nucleobase, the backbone, or both, depending on the location of the modification in the nucleotide. In some embodiments, the backbone modification is one provided in EP 2813570, which is herein incorporated by reference in its entirety. In some embodiments, the modified cap is one provided in US Pat. Pub. No. 20050287539, which is herein incorporated by reference in its entirety.

In some embodiments, the chemically modified nucleic acid (e.g., RNA, e.g., mRNA) comprises one or more of ARCA: anti-reverse cap analog (m27.3´-OGP3G), GP3G (Unmethylated Cap Analog), m7GP3G (Monomethylated Cap Analog), m32.2.7GP3G (Trimethylated Cap Analog), m5CTP (5´-methyl-cytidine triphosphate), m6ATP (N6-methyl-

adenosine-5′-triphosphate), s2UTP (2-thio-uridine triphosphate), and Ψ (pseudouridine triphosphate).

In some embodiments, the chemically modified nucleic acid comprises a 5′ cap, e.g.: a 7-methylguanosine cap (e.g., a O-Me-m7G cap); a hypermethylated cap analog; an NAD+-derived cap analog (e.g., as described in Kiledjian, Trends in Cell Biology 28, 454-464 (2018)); or a modified, e.g., biotinylated, cap analog (e.g., as described in Bednarek et al., Phil Trans R Soc B 373, 20180167 (2018)).

In some embodiments, the chemically modified nucleic acid comprises a 3′ feature selected from one or more of: a polyA tail; a 16-nucleotide long stem-loop structure flanked by unpaired 5 nucleotides (e.g., as described by Mannironi et al., Nucleic Acid Research 17, 9113-9126 (1989)); a triple-helical structure (e.g., as described by Brown et al., PNAS 109, 19202-19207 (2012)); a tRNA, Y RNA, or vault RNA structure (e.g., as described by Labno et al., Biochemica et Biophysica Acta 1863, 3125-3147 (2016)); incorporation of one or more deoxyribonucleotide triphosphates (dNTPs), 2'O-Methylated NTPs, or phosphorothioate-NTPs; a single nucleotide chemical modification (e.g., oxidation of the 3′ terminal ribose to a reactive aldehyde followed by conjugation of the aldehyde-reactive modified nucleotide); or chemical ligation to another nucleic acid molecule.

In some embodiments, the nucleic acid (e.g., template nucleic acid) comprises one or more modified nucleotides, e.g., selected from dihydrouridine, inosine, 7-methylguanosine, 5-methylcytidine (5mC), 5′ Phosphate ribothymidine, 2′-O-methyl ribothymidine, 2′-O-ethyl ribothymidine, 2′-fluoro ribothymidine, C-5 propynyl-deoxycytidine (pdC), C-5 propynyl-deoxyuridine (pdU), C-5 propynyl-cytidine (pC), C-5 propynyl-uridine (pU), 5-methyl cytidine, 5-methyl uridine, 5-methyl deoxycytidine, 5-methyl deoxyuridine methoxy, 2,6-diaminopurine, 5′-Dimethoxytrityl-N4-ethyl-2′-deoxycytidine, C-5 propynyl-f-cytidine (pfC), C-5 propynyl-f-uridine (pfU), 5-methyl f-cytidine, 5-methyl f-uridine, C-5 propynyl-m-cytidine (pmC), C-5 propynyl-f-uridine (pmU), 5-methyl m-cytidine, 5-methyl m-uridine, LNA (locked nucleic acid), MGB (minor groove binder) pseudouridine (Ψ), 1-N-methylpseudouridine (1-Me-Ψ), or 5-methoxyuridine (5-MO-U).

In some embodiments, the nucleic acid comprises a backbone modification, e.g., a modification to a sugar or phosphate group in the backbone. In some embodiments, the nucleic acid comprises a nucleobase modification.

In some embodiments, the nucleic acid comprises one or more chemically modified nucleotides of Table 13, one or more chemical backbone modifications of Table 14, one or more chemically modified caps of Table 15. For instance, in some embodiments, the nucleic acid comprises two or more (e.g., 3, 4, 5, 6, 7, 8, 9, or 10 or more) different types of chemical modifications. As an example, the nucleic acid may comprise two or more (e.g., 3, 4, 5, 6, 7, 8, 9, or 10 or more) different types of modified nucleobases, e.g., as described herein, e.g., in Table 13. Alternatively or in combination, the nucleic acid may comprise two or more (e.g., 3, 4, 5, 6, 7, 8, 9, or 10 or more) different types of backbone modifications, e.g., as described herein, e.g., in Table 14. Alternatively or in combination, the nucleic acid may comprise one or more modified cap, e.g., as described herein, e.g., in Table 15. For instance, in some embodiments, the nucleic acid comprises one or more type of modified nucleobase and one or more type of backbone modification; one or more type of modified nucleobase and one or more modified cap; one or more type of modified cap and one or more type of backbone modification; or one or more type of modified nucleobase, one or more type of backbone modification, and one or more type of modified cap.

In some embodiments, the nucleic acid comprises one or more (e.g., 2, 3, 4, 5, 6, 7, 8, 9, 10, 20, 30, 40, 50, 60, 70, 80, 90, 100, 150, 200, 250, 300, 350, 400, 450, 500, 600, 700, 800, 900, 1000, or more) modified nucleobases. In some embodiments, all nucleobases of the nucleic acid are modified. In some embodiments, the nucleic acid is modified at one or more (e.g., 2, 3, 4, 5, 6, 7, 8, 9, 10, 20, 30, 40, 50, 60, 70, 80, 90, 100, 150, 200, 250, 300, 350, 400, 450, 500, 600, 700, 800, 900, 1000, or more) positions in the backbone. In some embodiments, all backbone positions of the nucleic acid are modified.

Table 13. Modified nucleotides

5-aza-uridine	N2-methyl-6-thio-guanosine
2-thio-5-aza-midine	N2,N2-dimethyl-6-thio-guanosine
2-thiouridine	pyridin-4-one ribonucleoside
4-thio-pseudouridine	2-thio-5-aza-uridine
2-thio-pseudouridine	2-thiomidine
5-hydroxyuridine	4-thio-pseudomidine
3-methyluridine	2-thio-pseudowidine
5-carboxymethyl-uridine	3-methylmidine
1-carboxymethyl-pseudouridine	1-propynyl-pseudomidine
5-propynyl-uridine	1-methyl-1-deaza-pseudomidine

1-propynyl-pseudouridine	2-thio-1-methyl-1-deaza-pseudouridine
5-taurinomethyluridine	4-methoxy-pseudomidine
1-taurinomethyl-pseudouridine	5'-O-(1-Thiophosphate)-Adenosine
5-taurinomethyl-2-thio-uridine	5'-O-(1-Thiophosphate)-Cytidine
1-taurinomethyl-4-thio-uridine	5'-O-(1-thiophosphate)-Guanosine
5-methyl-uridine	5'-O-(1-Thiophophate)-Uridine
1-methyl-pseudouridine	5'-O-(1-Thiophosphate)-Pseudouridine
4-thio-1-methyl-pseudouridine	2'-O-methyl-Adenosine
2-thio-1-methyl-pseudouridine	2'-O-methyl-Cytidine

The nucleotides comprising the template of the gene modifying system can be natural or modified bases, or a combination thereof. For example, the template may contain pseudouridine, dihydrouridine, inosine, 7-methylguanosine, or other modified bases. In some embodiments, the template may contain locked nucleic acid nucleotides. In some embodiments, the modified bases used in the template do not inhibit the reverse transcription of the template. In some

embodiments, the modified bases used in the template may improve reverse transcription, e.g., specificity or fidelity.

In some embodiments, an RNA component of the system (e.g., a template RNA or a gRNA) comprises one or more nucleotide modifications. In some embodiments, the modification pattern of a gRNA can significantly affect *in vivo* activity compared to unmodified or end-modified guides (e.g., as shown in Figure 1D from Finn et al. *Cell Rep* 22(9):2227-2235 (2018); incorporated herein by reference in its entirety). Without wishing to be bound by theory, this process may be due, at least in part, to a stabilization of the RNA conferred by the modifications. Non-limiting examples of such modifications may include 2'-O-methyl (2'-O-Me), 2'-0-(2-methoxyethyl) (2'-0-MOE), 2'- fluoro (2'-F), phosphorothioate (PS) bond between nucleotides, G-C substitutions, and inverted abasic linkages between nucleotides and equivalents thereof.

In some embodiments, the template RNA (e.g., at the portion thereof that binds a target site) or the guide RNA comprises a 5´ terminus region. In some embodiments, the template RNA or the guide RNA does not comprise a 5´ terminus region. In some embodiments, the 5´ terminus region comprises a gRNA spacer region, e.g., as described with respect to sgRNA in Briner AE et al, Molecular Cell 56: 333-339 (2014) (incorporated herein by reference in its entirety; applicable herein, e.g., to all guide RNAs). In some embodiments, the 5´ terminus region comprises a 5´ end modification. In some embodiments, a 5´ terminus region with or without a spacer region may be associated with a crRNA, trRNA, sgRNA and/or dgRNA. The gRNA spacer region can, in some instances, comprise a guide region, guide domain, or targeting domain.

In some embodiments, the template RNAs (e.g., at the portion thereof that binds a target site) or guide RNAs described herein comprises any of the sequences shown in Table 4 of WO2018107028A1, incorporated herein by reference in its entirety. In some embodiments, where a sequence shows a guide and/or spacer region, the composition may comprise this region or not. In some embodiments, a guide RNA comprises one or more of the modifications of any of the sequences shown in Table 4 of WO2018107028A1, e.g., as identified therein by a SEQ ID NO. In embodiments, the nucleotides may be the same or different, and/or the modification pattern shown may be the same or similar to a modification pattern of a guide sequence as shown

in Table 4 of WO2018107028A1. In some embodiments, a modification pattern includes the relative position and identity of modifications of the gRNA or a region of the gRNA (e.g. 5´ terminus region, lower stem region, bulge region, upper stem region, nexus region, hairpin 1 region, hairpin 2 region, 3´ terminus region). In some embodiments, the modification pattern contains at least 50%, 55%, 60%, 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99%, or 100% of the modifications of any one of the sequences shown in the sequence column of Table 4 of WO2018107028A1, and/or over one or more regions of the sequence. In some embodiments, the modification pattern is at least 50%, 55%, 60%, 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99%, or 100% identical to the modification pattern of any one of the sequences shown in the sequence column of Table 4 of WO2018107028A1. In some embodiments, the modification pattern is at least 50%, 55%, 60%, 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99%, or 100% identical over one or more regions of the sequence shown in Table 4 of WO2018107028A1, e.g., in a 5 ' terminus region, lower stem region, bulge region, upper stem region, nexus region, hairpin 1 region, hairpin 2 region, and/or 3´ terminus region. In some embodiments, the modification pattern is least 50%, 55%, 60%, 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99%, or 100% identical to the modification pattern of a sequence over the 5 ' terminus region. In some embodiments, the modification pattern is least 50%, 55%, 60%, 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99%, or 100% identical over the lower stem. In some embodiments, the modification pattern is least 50%, 55%, 60%, 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99%, or 100% identical over the bulge. In some embodiments, the modification pattern is least 50%, 55%, 60%, 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99%, or 100% identical over the upper stem. In some embodiments, the modification pattern is least 50%, 55%, 60%, 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99%, or 100% identical over the nexus. In some embodiments, the modification pattern is least 50%, 55%, 60%, 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99%, or 100% identical over the hairpin 1. In some embodiments, the modification pattern is least 50%, 55%, 60%, 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99%, or 100% identical over the hairpin 2. In some embodiments, the modification pattern is least 50%, 55%, 60%, 70%, 75%, 80%, 85%, 90%, 95%, 96%, 97%, 98%, 99%, or 100% identical over the 3 ' terminus. In some embodiments, the modification pattern differs from the modification pattern of a sequence of Table 4 of WO2018107028A1, or a region (e.g. 5´ terminus, lower stem, bulge, upper stem, nexus, hairpin

1, hairpin 2, 3´ terminus) of such a sequence, e.g., at 0, 1, 2, 3, 4, 5, 6, or more nucleotides. In some embodiments, the gRNA comprises modifications that differ from the modifications of a sequence of Table 4 of WO2018107028A1, e.g., at 0, 1, 2, 3, 4, 5, 6, or more nucleotides. In some embodiments, the gRNA comprises modifications that differ from modifications of a region (e.g. 5 ' terminus, lower stem, bulge, upper stem, nexus, hairpin 1, hairpin 2, 3´ terminus) of a sequence of Table 4 of WO2018107028A1, e.g., at 0, 1, 2, 3, 4, 5, 6, or more nucleotides.

In some embodiments, the template RNAs (e.g., at the portion thereof that binds a target site) or the gRNA comprises a 2'-O-methyl (2'-O-Me) modified nucleotide. In some embodiments, the gRNA comprises a 2'-O-(2-methoxy ethyl) (2'-O-moe) modified nucleotide. In some embodiments, the gRNA comprises a 2'-fluoro (2'- F) modified nucleotide. In some embodiments, the gRNA comprises a phosphorothioate (PS) bond between nucleotides. In some embodiments, the gRNA comprises a 5´ end modification, a 3´ end modification, or 5´ and 3´ end modifications. In some embodiments, the 5´ end modification comprises a phosphorothioate (PS) bond between nucleotides. In some embodiments, the 5´ end modification comprises a 2'-O-methyl (2'-O-Me), 2'-O-(2-methoxy ethyl) (2'-O-MOE), and/or 2'-fluoro (2'-F) modified nucleotide. In some embodiments, the 5´ end modification comprises at least one phosphorothioate (PS) bond and one or more of a 2'-O-methyl (2'-O- Me), 2'-O-(2-methoxyethyl) (2'-O-MOE), and/or 2'-fluoro (2'-F) modified nucleotide. The end modification may comprise a phosphorothioate (PS), 2'-O-methyl (2'-O-Me), 2'-O-(2- methoxyethyl) (2'-O-MOE), and/or 2'-fluoro (2'-F) modification. Equivalent end modifications are also encompassed by embodiments described herein. In some embodiments, the template RNA or gRNA comprises an end modification in combination with a modification of one or more regions of the template RNA or gRNA. Additional exemplary modifications and methods for protecting RNA, e.g., gRNA, and formulae thereof, are described in WO2018126176A1, which is incorporated herein by reference in its entirety.

In some embodiments, a template RNA described herein comprises three phosphorothioate linkages at the 5’ end and three phosphorothioate linkages at the 3’ end. In some embodiments, a template RNA described herein comprises three 2’-O-methyl ribonucleotides at the 5’ end and three 2’-O-methyl ribonucleotides at the 3’ end. In some embodiments, the 5’ most three nucleotides of the template RNA are 2’-O-methyl

ribonucleotides, the 5’ most three internucleotide linkages of the template RNA are phosphorothioate linkages, the 3’ most three nucleotides of the template RNA are 2’-O-methyl ribonucleotides, and the 3’ most three internucleotide linkages of the template RNA are phosphorothioate linkages. In some embodiments, the template RNA comprises alternating blocks of ribonucleotides and 2’-O-methyl ribonucleotides, for instance, blocks of between 12 and 28 nucleotides in length. In some embodiments, the central portion of the template RNA comprises the alternating blocks and the 5’ and 3’ ends each comprise three 2’-O-methyl ribonucleotides and three phosphorothioate linkages.

In some embodiments, structure-guided and systematic approaches are used to introduce modifications (e.g., 2′-OMe-RNA, 2′-F-RNA, and PS modifications) to a template RNA or guide RNA, for example, as described in Mir et al. *Nat Commun* 9:2641 (2018) (incorporated by reference herein in its entirety). In some embodiments, the incorporation of 2′-F-RNAs increases thermal and nuclease stability of RNA:RNA or RNA:DNA duplexes, e.g., while minimally interfering with C3′-endo sugar puckering. In some embodiments, 2′-F may be better tolerated than 2′-OMe at positions where the 2′-OH is important for RNA:DNA duplex stability. In some embodiments, a crRNA comprises one or more modifications that do not reduce Cas9 activity, e.g., C10, C20, or C21 (fully modified), e.g., as described in Supplementary Table 1 of Mir et al. *Nat Commun* 9:2641 (2018), incorporated herein by reference in its entirety. In some embodiments, a tracrRNA comprises one or more modifications that do not reduce Cas9 activity, e.g., T2, T6, T7, or T8 (fully modified) of Supplementary Table 1 of Mir et al. *Nat Commun* 9:2641 (2018). In some embodiments, a crRNA comprises one or more modifications (e.g., as described herein) may be paired with a tracrRNA comprising one or more modifications, e.g., C20 and T2. In some embodiments, a gRNA comprises a chimera, e.g., of a crRNA and a tracrRNA (e.g., Jinek et al. *Science* 337(6096):816-821 (2012)). In embodiments, modifications from the crRNA and tracrRNA are mapped onto the single-guide chimera, e.g., to produce a modified gRNA with enhanced stability.

In some embodiments, gRNA molecules may be modified by the addition or subtraction of the naturally occurring structural components, e.g., hairpins. In some embodiments, a gRNA may comprise a gRNA with one or more 3´ hairpin elements deleted, e.g., as described in WO2018106727, incorporated herein by reference in its entirety. In some embodiments, a

gRNA may contain an added hairpin structure, e.g., an added hairpin structure in the spacer region, which was shown to increase specificity of a CRISPR-Cas system in the teachings of Kocak et al. *Nat Biotechnol* 37(6):657-666 (2019). Additional modifications, including examples of shortened gRNA and specific modifications improving *in vivo* activity, can be found in US20190316121, incorporated herein by reference in its entirety.

In some embodiments, structure-guided and systematic approaches (e.g., as described in Mir et al. *Nat Commun* 9:2641 (2018); incorporated herein by reference in its entirety) are employed to find modifications for the template RNA. In embodiments, the modifications are identified with the inclusion or exclusion of a guide region of the template RNA. In some embodiments, a structure of polypeptide bound to template RNA is used to determine non-protein-contacted nucleotides of the RNA that may then be selected for modifications, e.g., with lower risk of disrupting the association of the RNA with the polypeptide. Secondary structures in a template RNA can also be predicted *in silico* by software tools, e.g., the RNAstructure tool available at rna.urmc.rochester.edu/RNAstructureWeb (Bellaousov et al. *Nucleic Acids Res* 41:W471-W474 (2013); incorporated by reference herein in its entirety), e.g., to determine secondary structures for selecting modifications, e.g., hairpins, stems, and/or bulges.

Production of Compositions and Systems

As will be appreciated by one of skill, methods of designing and constructing nucleic acid constructs and proteins or polypeptides (such as the systems, constructs and polypeptides described herein) are routine in the art. Generally, recombinant methods may be used. See, in general, Smales & James (Eds.), *Therapeutic Proteins: Methods and Protocols* (Methods in Molecular Biology), Humana Press (2005); and Crommelin, Sindelar & Meibohm (Eds.), *Pharmaceutical Biotechnology: Fundamentals and Applications*, Springer (2013). Methods of designing, preparing, evaluating, purifying and manipulating nucleic acid compositions are described in Green and Sambrook (Eds.), *Molecular Cloning: A Laboratory Manual* (Fourth Edition), Cold Spring Harbor Laboratory Press (2012).

The disclosure provides, in part, a nucleic acid, e.g., vector, encoding a gene modifying polypeptide described herein, a template nucleic acid described herein, or both. In some embodiments, a vector comprises a selective marker, e.g., an antibiotic resistance marker. In some embodiments, the antibiotic resistance marker is a kanamycin resistance marker. In some embodiments, the antibiotic resistance marker does not confer resistance to beta-lactam

antibiotics. In some embodiments, the vector does not comprise an ampicillin resistance marker. In some embodiments, the vector comprises a kanamycin resistance marker and does not comprise an ampicillin resistance marker. In some embodiments, a vector encoding a gene modifying polypeptide is integrated into a target cell genome (e.g., upon administration to a target cell, tissue, organ, or subject). In some embodiments, a vector encoding a gene modifying polypeptide is not integrated into a target cell genome (e.g., upon administration to a target cell, tissue, organ, or subject). In some embodiments, a vector encoding a template nucleic acid (e.g., template RNA) is not integrated into a target cell genome (e.g., upon administration to a target cell, tissue, organ, or subject). In some embodiments, if a vector is integrated into a target site in a target cell genome, the selective marker is not integrated into the genome. In some embodiments, if a vector is integrated into a target site in a target cell genome, genes or sequences involved in vector maintenance (e.g., plasmid maintenance genes) are not integrated into the genome. In some embodiments, if a vector is integrated into a target site in a target cell genome, transfer regulating sequences (e.g., inverted terminal repeats, e.g., from an AAV) are not integrated into the genome. In some embodiments, administration of a vector (e.g., encoding a gene modifying polypeptide described herein, a template nucleic acid described herein, or both) to a target cell, tissue, organ, or subject results in integration of a portion of the vector into one or more target sites in the genome(s) of said target cell, tissue, organ, or subject. In some embodiments, less than 99, 95, 90, 80, 70, 60, 50, 40, 30, 20, 10, 5, 4, 3, 2, or 1% of target sites (e.g., no target sites) comprising integrated material comprise a selective marker (e.g., an antibiotic resistance gene), a transfer regulating sequence (e.g., an inverted terminal repeat, e.g., from an AAV), or both from the vector.

Exemplary methods for producing a therapeutic pharmaceutical protein or polypeptide described herein involve expression in mammalian cells, although recombinant proteins can also be produced using insect cells, yeast, bacteria, or other cells under control of appropriate promoters. Mammalian expression vectors may comprise non-transcribed elements such as an origin of replication, a suitable promoter, and other 5' or 3' flanking non-transcribed sequences, and 5' or 3' non-translated sequences such as necessary ribosome binding sites, a polyadenylation site, splice donor and acceptor sites, and termination sequences. DNA sequences derived from the SV40 viral genome, for example, SV40 origin, early promoter, splice, and polyadenylation sites may be used to provide other genetic elements required for expression of a heterologous

DNA sequence. Appropriate cloning and expression vectors for use with bacterial, fungal, yeast, and mammalian cellular hosts are described in Green & Sambrook, *Molecular Cloning: A Laboratory Manual* (Fourth Edition), Cold Spring Harbor Laboratory Press (2012).

Various mammalian cell culture systems can be employed to express and manufacture recombinant protein. Examples of mammalian expression systems include CHO, COS, HEK293, HeLA, and BHK cell lines. Processes of host cell culture for production of protein therapeutics are described in Zhou and Kantardjieff (Eds.), *Mammalian Cell Cultures for Biologics Manufacturing (Advances in Biochemical Engineering/Biotechnology)*, Springer (2014). Compositions described herein may include a vector, such as a viral vector, e.g., a lentiviral vector, encoding a recombinant protein. In some embodiments, a vector, e.g., a viral vector, may comprise a nucleic acid encoding a recombinant protein.

Purification of protein therapeutics is described in Franks, Protein Biotechnology: *Isolation, Characterization, and Stabilization*, Humana Press (2013); and in Cutler, *Protein Purification Protocols (Methods in Molecular Biology)*, Humana Press (2010).

The disclosure also provides compositions and methods for the production of template nucleic acid molecules (e.g., template RNAs) with specificity for a gene modifying polypeptide and/or a genomic target site. In an aspect, the method comprises production of RNA segments including an upstream homology segment, a heterologous object sequence segment, a gene modifying polypeptide binding motif, and a gRNA segment.

Therapeutic Applications

In some embodiments, a gene modifying system as described herein can be used to modify a cell (e.g., an animal cell, plant cell, or fungal cell). In some embodiments, a gene modifying system as described herein can be used to modify a mammalian cell (e.g., a human cell). In some embodiments, a gene modifying system as described herein can be used to modify a cell from a livestock animal (e.g., a cow, horse, sheep, goat, pig, llama, alpaca, camel, yak, chicken, duck, goose, or ostrich). In some embodiments, a gene modifying system as described herein can be used as a laboratory tool or a research tool, or used in a laboratory method or research method, e.g., to modify an animal cell, e.g., a mammalian cell (e.g., a human cell), a plant cell, or a fungal cell.

By integrating coding genes into a RNA sequence template, the gene modifying system can address therapeutic needs, for example, by providing expression of a therapeutic transgene in individuals with loss-of-function mutations, by replacing gain-of-function mutations with normal transgenes, by providing regulatory sequences to eliminate gain-of-function mutation expression, and/or by controlling the expression of operably linked genes, transgenes and systems thereof. In certain embodiments, the RNA sequence template encodes a promotor region specific to the therapeutic needs of the host cell, for example a tissue specific promotor or enhancer. In still other embodiments, a promotor can be operably linked to a coding sequence.

Accordingly, provided herein are methods for treating phenylketonuria (PKU) or hyperphenylalaninemia (e.g., mild or severe hyperphenylalaninemia) in a subject in need thereof. In some embodiments, treatment results in amelioration of one or more symptoms associated with PKU or hyperphenylalaninemia.

In some embodiments, a system herein is used to treat a subject having a mutation in R408 (e.g., R408W), R261 (e.g., R261Q), R243 (e.g., R243Q), and/or IVS10-11G (e.g., IVS10-11G>A).

In some embodiments, treatment with a system disclosed herein results in correction of the R408W, R261Q, R243Q, and/or IVS10-11G>A mutation in between about 5-50% (e.g., about 5-10%, 10-20%, 20-30%, 30-40%, 40-50%, or about 10%) of cells. In some embodiments, treatment with a system disclosed herein results in correction of the R408W, R261Q, R243Q, and/or IVS10-11G>A mutation in between about 5-50% (e.g., about 5-10%, 10-20%, 20-30%, 30-40%, 40-50%, or about 10%) of DNA from the treated cells.

In some embodiments, treatment with a gene modifying system described herein results in one or more of:

(a) an increase in phenylalanine hydroxylase (PAH) activity, efficiency, and/or function;

(b) a decrease in the concentration of phenylalanine in the blood and/or cerebrospinal fluid;

(c) increase in the concentration of tyrosine in the blood

(d) a restoration of normal synthesis of dopamine, norepinephrine, and/or melanin;

(e) a reduction in ureagenesis; and/or

(f) an improvement in protein retention and/or Phe utilization

as compared to a subject having PKU that has not been treated with a gene modifying system described herein.

Administration and Delivery

The compositions and systems described herein may be used *in vitro* or *in vivo*. In some embodiments the system or components of the system are delivered to cells (e.g., mammalian cells, e.g., human cells), e.g., *in vitro* or *in vivo*. In some embodiments, the cells are eukaryotic cells, e.g., cells of a multicellular organism, e.g., an animal, e.g., a mammal (e.g., human, swine, bovine), a bird (e.g., poultry, such as chicken, turkey, or duck), or a fish. In some embodiments, the cells are non-human animal cells (e.g., a laboratory animal, a livestock animal, or a companion animal). In some embodiments, the cell is a stem cell (e.g., a hematopoietic stem cell), a fibroblast, or a T cell. In some embodiments, the cell is an immune cell, e.g., a T cell (e.g., a Treg, CD4, CD8, γδ, or memory T cell), B cell (e.g., memory B cell or plasma cell), or NK cell. In some embodiments, the cell is a non-dividing cell, e.g., a non-dividing fibroblast or non-dividing T cell. In some embodiments, the cell is an HSC and p53 is not upregulated or is upregulated by less than 10%, 5%, 2%, or 1%, e.g., as determined according to the method described in Example 30 of PCT/US2019/048607. The skilled artisan will understand that the components of the gene modifying system may be delivered in the form of polypeptide, nucleic acid (e.g., DNA, RNA), and combinations thereof.

In one embodiment the system and/or components of the system are delivered as nucleic acid. For example, the gene modifying polypeptide may be delivered in the form of a DNA or RNA encoding the polypeptide, and the template RNA may be delivered in the form of RNA or its complementary DNA to be transcribed into RNA. In some embodiments the system or components of the system are delivered on 1, 2, 3, 4, or more distinct nucleic acid molecules. In some embodiments the system or components of the system are delivered as a combination of DNA and RNA. In some embodiments the system or components of the system are delivered as a combination of DNA and protein. In some embodiments the system or components of the system are delivered as a combination of RNA and protein. In some embodiments the gene modifying polypeptide is delivered as a protein.

In some embodiments the system or components of the system are delivered to cells, e.g. mammalian cells or human cells, using a vector. The vector may be, e.g., a plasmid or a virus. In some embodiments, delivery is *in vivo, in vitro, ex vivo,* or *in situ.* In some embodiments the virus is an adeno associated virus (AAV), a lentivirus, or an adenovirus. In some embodiments the system or components of the system are delivered to cells with a viral-like particle or a virosome. In some embodiments the delivery uses more than one virus, viral-like particle or virosome.

In one embodiment, the compositions and systems described herein can be formulated in liposomes or other similar vesicles. Liposomes are spherical vesicle structures composed of a uni- or multilamellar lipid bilayer surrounding internal aqueous compartments and a relatively impermeable outer lipophilic phospholipid bilayer. Liposomes may be anionic, neutral or cationic. Liposomes are biocompatible, nontoxic, can deliver both hydrophilic and lipophilic drug molecules, protect their cargo from degradation by plasma enzymes, and transport their load across biological membranes and the blood brain barrier (BBB) (see, e.g., Spuch and Navarro, Journal of Drug Delivery, vol. 2011, Article ID 469679, 12 pages, 2011. doi:10.1155/2011/469679 for review).

Vesicles can be made from several different types of lipids; however, phospholipids are most commonly used to generate liposomes as drug carriers. Methods for preparation of multilamellar vesicle lipids are known in the art (see for example U.S. Pat. No. 6,693,086, the teachings of which relating to multilamellar vesicle lipid preparation are incorporated herein by reference). Although vesicle formation can be spontaneous when a lipid film is mixed with an aqueous solution, it can also be expedited by applying force in the form of shaking by using a homogenizer, sonicator, or an extrusion apparatus (see, e.g., Spuch and Navarro, Journal of Drug Delivery, vol. 2011, Article ID 469679, 12 pages, 2011. doi:10.1155/2011/469679 for review). Extruded lipids can be prepared by extruding through filters of decreasing size, as described in Templeton et al., Nature Biotech, 15:647-652, 1997, the teachings of which relating to extruded lipid preparation are incorporated herein by reference.

A variety of nanoparticles can be used for delivery, such as a liposome, a lipid nanoparticle, a cationic lipid nanoparticle, an ionizable lipid nanoparticle, a polymeric nanoparticle, a gold nanoparticle, a dendrimer, a cyclodextrin nanoparticle, a micelle, or a combination of the foregoing.

Lipid nanoparticles are an example of a carrier that provides a biocompatible and biodegradable delivery system for the pharmaceutical compositions described herein. Nanostructured lipid carriers (NLCs) are modified solid lipid nanoparticles (SLNs) that retain the characteristics of the SLN, improve drug stability and loading capacity, and prevent drug leakage. Polymer nanoparticles (PNPs) are an important component of drug delivery. These nanoparticles can effectively direct drug delivery to specific targets and improve drug stability and controlled drug release. Lipid–polymer nanoparticles (PLNs), a type of carrier that combines liposomes and polymers, may also be employed. These nanoparticles possess the complementary advantages of PNPs and liposomes. A PLN is composed of a core–shell structure; the polymer core provides a stable structure, and the phospholipid shell offers good biocompatibility. As such, the two components increase the drug encapsulation efficiency rate, facilitate surface modification, and prevent leakage of water-soluble drugs. For a review, see, e.g., Li et al. 2017, Nanomaterials 7, 122; doi:10.3390/nano7060122.

Exosomes can also be used as drug delivery vehicles for the compositions and systems described herein. For a review, see Ha et al. July 2016. Acta Pharmaceutica Sinica B. Volume 6, Issue 4, Pages 287-296; https://doi.org/10.1016/j.apsb.2016.02.001.

Fusosomes interact and fuse with target cells, and thus can be used as delivery vehicles for a variety of molecules. They generally consist of a bilayer of amphipathic lipids enclosing a lumen or cavity and a fusogen that interacts with the amphipathic lipid bilayer. The fusogen component has been shown to be engineerable in order to confer target cell specificity for the fusion and payload delivery, allowing the creation of delivery vehicles with programmable cell specificity (see for example Patent Application WO2020014209, the teachings of which relating to fusosome design, preparation, and usage are incorporated herein by reference).

In some embodiments, the protein component(s) of the gene modifying system may be pre-associated with the template nucleic acid (e.g., template RNA). For example, in some embodiments, the gene modifying polypeptide may be first combined with the template nucleic acid (e.g., template RNA) to form a ribonucleoprotein (RNP) complex. In some embodiments, the RNP may be delivered to cells via, e.g., transfection, nucleofection, virus, vesicle, LNP, exosome, fusosome.

A gene modifying system can be introduced into cells, tissues and multicellular organisms. In some embodiments the system or components of the system are delivered to the cells via mechanical means or physical means.

Formulation of protein therapeutics is described in Meyer (Ed.), *Therapeutic Protein Drug Products: Practical Approaches to formulation in the Laboratory, Manufacturing, and the Clinic*, Woodhead Publishing Series (2012).

Tissue Specific Activity/Administration

In some embodiments, a system described herein can make use of one or more feature (e.g., a promoter or microRNA binding site) to limit activity in off-target cells or tissues.

In some embodiments, a nucleic acid described herein (e.g., a template RNA or a DNA encoding a template RNA) comprises a promoter sequence, e.g., a tissue specific promoter sequence. In some embodiments, the tissue-specific promoter is used to increase the target-cell specificity of a gene modifying system. For instance, the promoter can be chosen on the basis that it is active in a target cell type but not active in (or active at a lower level in) a non-target cell type. Thus, even if the promoter integrated into the genome of a non-target cell, it would not drive expression (or only drive low level expression) of an integrated gene. A system having a tissue-specific promoter sequence in the template RNA may also be used in combination with a microRNA binding site, e.g., in the template RNA or a nucleic acid encoding a gene modifying protein, e.g., as described herein. A system having a tissue-specific promoter sequence in the template RNA may also be used in combination with a DNA encoding a gene modifying polypeptide, driven by a tissue-specific promoter, e.g., to achieve higher levels of gene modifying protein in target cells than in non-target cells. In some embodiments, e.g., for liver indications, a tissue-specific promoter is selected from Table 3 of WO2020014209, incorporated herein by reference.

In some embodiments, a nucleic acid described herein (e.g., a template RNA or a DNA encoding a template RNA) comprises a microRNA binding site. In some embodiments, the microRNA binding site is used to increase the target-cell specificity of a gene modifying system. For instance, the microRNA binding site can be chosen on the basis that is recognized by a miRNA that is present in a non-target cell type, but that is not present (or is present at a reduced level relative to the non-target cell) in a target cell type. Thus, when the template RNA is present

in a non-target cell, it would be bound by the miRNA, and when the template RNA is present in a target cell, it would not be bound by the miRNA (or bound but at reduced levels relative to the non-target cell). While not wishing to be bound by theory, binding of the miRNA to the template RNA may interfere with its activity, e.g., may interfere with insertion of the heterologous object sequence into the genome. Accordingly, the system would edit the genome of target cells more efficiently than it edits the genome of non-target cells, e.g., the heterologous object sequence would be inserted into the genome of target cells more efficiently than into the genome of non-target cells, or an insertion or deletion is produced more efficiently in target cells than in non-target cells. A system having a microRNA binding site in the template RNA (or DNA encoding it) may also be used in combination with a nucleic acid encoding a gene modifying polypeptide, wherein expression of the gene modifying polypeptide is regulated by a second microRNA binding site, e.g., as described herein. In some embodiments, e.g., for liver indications, a miRNA is selected from Table 4 of WO2020014209, incorporated herein by reference.

In some embodiments, the template RNA comprises a microRNA sequence, an siRNA sequence, a guide RNA sequence, or a piwi RNA sequence.

Promoters

In some embodiments, one or more promoter or enhancer elements are operably linked to a nucleic acid encoding a gene modifying protein or a template nucleic acid, e.g., that controls expression of the heterologous object sequence. In certain embodiments, the one or more promoter or enhancer elements comprise cell-type or tissue specific elements. In some embodiments, the promoter or enhancer is the same or derived from the promoter or enhancer that naturally controls expression of the heterologous object sequence. For example, the ornithine transcarbomylase promoter and enhancer may be used to control expression of the ornithine transcarbomylase gene in a system or method provided by the invention for correcting ornithine transcarbomylase deficiencies. In some embodiments, the promoter is a promoter of Table 16 or 17 or a functional fragment or variant thereof.

Exemplary tissue specific promoters that are commercially available can be found, for example, at a uniform resource locator (e.g., www.invivogen.com/tissue-specific-promoters). In some embodiments, a promoter is a native promoter or a minimal promoter, e.g., which consists

of a single fragment from the 5´ region of a given gene. In some embodiments, a native promoter comprises a core promoter and its natural 5´ UTR. In some embodiments, the 5´ UTR comprises an intron. In other embodiments, these include composite promoters, which combine promoter elements of different origins or were generated by assembling a distal enhancer with a minimal promoter of the same origin.

Exemplary cell or tissue specific promoters are provided in the tables, below, and exemplary nucleic acid sequences encoding them are known in the art and can be readily accessed using a variety of resources, such as the NCBI database, including RefSeq, as well as the Eukaryotic Promoter Database (//epd.epfl.ch//index.php).

Table 16. Exemplary cell or tissue-specific promoters

Promoter	**Target cells**
B29 Promoter	B cells
CD14 Promoter	Monocytic Cells
CD43 Promoter	Leukocytes and platelets
CD45 Promoter	Hematopoeitic cells
CD68 promoter	macrophages
Desmin promoter	muscle cells
Elastase-1 promoter	pancreatic acinar cells
Endoglin promoter	endothelial cells
fibronectin promoter	differentiating cells, healing tissue
Flt-1 promoter	endothelial cells
GFAP promoter	Astrocytes
GPIIB promoter	megakaryocytes
ICAM-2 Promoter	Endothelial cells
INF-Beta promoter	Hematopoeitic cells
Mb promoter	muscle cells
Nphs1 promoter	podocytes
OG-2 promoter	Osteoblasts, Odonblasts
SP-B promoter	Lung
Syn1 promoter	Neurons
WASP promoter	Hematopoeitic cells
SV40/bAlb promoter	Liver

SV40/bAlb promoter	Liver
SV40/Cd3 promoter	Leukocytes and platelets
SV40/CD45 promoter	hematopoeitic cells
NSE/RU5' promoter	Mature Neurons

Table 17. Additional exemplary cell or tissue-specific promoters

Promoter	**Gene Description**	**Gene Specificity**
APOA2	Apolipoprotein A-II	Hepatocytes (from hepatocyte progenitors)
SERPINA 1 (hAAT)	Serpin peptidase inhibitor, clade A (alpha-1 antiproteinase, antitrypsin), member 1 (also named alpha 1 anti-tryps in)	Hepatocytes (from definitive endoderm stage)
CYP3A	Cytochrome P450, family 3, subfamily A, polypeptide	Mature Hepatocytes
MIR122	MicroRNA 122	Hepatocytes (from early stage embryonic liver cells) and endoderm
Pancreatic specific promoters		
Promoter	**Gene Description**	**Gene Specificity**
INS	Insulin	Pancreatic beta cells (from definitive endoderm stage)
IRS2	Insulin receptor substrate 2	Pancreatic beta cells
Pdx1	Pancreatic and duodenal homeobox 1	Pancreas (from definitive endoderm stage)
Alx3	Aristaless-like homeobox 3	Pancreatic beta cells (from definitive endoderm stage)
Ppy	Pancreatic polypeptide	PP pancreatic cells (gamma cells)
Cardiac specific promoters		
Promoter	**Gene Description**	**Gene Specificity**
Myh6 (aMHC)	Myosin, heavy chain 6, cardiac muscle, alpha	Late differentiation marker of cardiac muscle cells (atrial specificity)
MYL2 (MLC-2v)	Myosin, light chain 2, regulatory, cardiac, slow	Late differentiation marker of cardiac muscle cells (ventricular specificity)

ITNNl3 (cTnl)	Troponin I type 3 (cardiac)	Cardiomyocytes (from immature state)
ITNNl3 (cTnl)	Troponin I type 3 (cardiac)	Cardiomyocytes (from immature state)
NPPA (ANF)	Natriuretic peptide precursor A (also named Atrial Natriuretic Factor)	Atrial specificity in adult cells
Slc8a1 (Ncx1)	Solute carrier family 8 (sodium/calcium exchanger), member 1	Cardiomyocytes from early developmental stages
CNS specific promoters		
Promoter	**Gene Description**	**Gene Specificity**
SYN1 (hSyn)	Synapsin I	Neurons
GFAP	Glial fibrillary acidic protein	Astrocytes
INA	lnternexin neuronal intermediate filament protein, alpha (a-internexin)	Neuroprogenitors
NES	Nestin	Neuroprogenitors and ectoderm
MOBP	Myelin-associated oligodendrocyte basic protein	Oligodendrocytes
MBP	Myelin basic protein	Oligodendrocytes
TH	Tyrosine hydroxylase	Dopaminergic neurons
FOXA2 (HNF3 beta)	Forkhead box A2	Dopaminergic neurons (also used as a marker of endoderm)
Skin specific promoters		
Promoter	**Gene Description**	**Gene Specificity**
FLG	Filaggrin	Keratinocytes from granular layer
K14	Keratin 14	Keratinocytes from granular and basal layers
TGM3	Transglutaminase 3	Keratinocytes from granular layer
Immune cell specific promoters		
Promoter	**Gene Description**	**Gene Specificity**
ITGAM (CD11B)	lntegrin, alpha M (complement component 3 receptor 3 subunit)	Monocytes, macrophages , granulocytes , natural killer cells
Urogential cell specific promoters		
Promoter	**Gene Description**	**Gene Specificity**
Pbsn	Probasin	Prostatic epithelium

Upk2	Uroplakin 2	Bladder
Sbp	Spermine binding protein	Prostate
Fer1l4	Fer-1-like 4	Bladder
Endothelial cell specific promoters		
Promoter	**Gene Description**	**Gene Specificity**
ENG	Endoglin	Endothelial cells
Pluripotent and embryonic cell specific promoters		
Promoter	**Gene Description**	**Gene Specificity**
Oct4 (POU5F1)	POU class 5 homeobox 1	Pluripotent cells (germ cells, ES cells, iPS cells)
NANOG	Nanog homeobox	Pluripotent cells (ES cells, iPS cells)
Synthetic Oct4	Synthetic promoter based on a Oct-4 core enhancer element	Pluripotent cells (ES cells, iPS cells)
T brachyury	Brachyury	Mesoderm
NES	Nestin	Neuroprogenitors and Ectoderm
SOX17	SRY (sex determining region Y)-box 17	Endoderm
FOXA2 (HNFJ beta)	Forkhead box A2	Endoderm (also used as a marker of dopaminergic neurons)
MIR122	MicroRNA 122	Endoderm and hepatocytes (from early stage embryonic liver cells~

Depending on the host/vector system utilized, any of a number of suitable transcription and translation control elements, including constitutive and inducible promoters, transcription enhancer elements, transcription terminators, etc. may be used in the expression vector (see e.g., Bitter et al. (1987) *Methods in Enzymology*, 153:516-544; incorporated herein by reference in its entirety).

In some embodiments, a nucleic acid encoding a gene modifying protein or template nucleic acid is operably linked to a control element, e.g., a transcriptional control element, such as a promoter. The transcriptional control element may, in some embodiment, be functional in either a eukaryotic cell, e.g., a mammalian cell; or a prokaryotic cell (e.g., bacterial or archaeal cell). In some embodiments, a nucleotide sequence encoding a polypeptide is operably linked to

multiple control elements, e.g., that allow expression of the nucleotide sequence encoding the polypeptide in both prokaryotic and eukaryotic cells.

For illustration purposes, examples of spatially restricted promoters include, but are not limited to, neuron-specific promoters, adipocyte-specific promoters, cardiomyocyte-specific promoters, smooth muscle-specific promoters, photoreceptor-specific promoters, etc. Neuron-specific spatially restricted promoters include, but are not limited to, a neuron-specific enolase (NSE) promoter (see, e.g., EMBL HSENO2, X51956); an aromatic amino acid decarboxylase (AADC) promoter, a neurofilament promoter (see, e.g., GenBank HUMNFL, L04147); a synapsin promoter (see, e.g., GenBank HUMSYNIB, M55301); a thy-1 promoter (see, e.g., Chen et al. (1987) Cell 51:7-19; and Llewellyn, et al. (2010) Nat. Med. 16(10):1161-1166); a serotonin receptor promoter (see, e.g., GenBank S62283); a tyrosine hydroxylase promoter (TH) (see, e.g., Oh et al. (2009) Gene Ther 16:437; Sasaoka et al. (1992) Mol. Brain Res. 16:274; Boundy et al. (1998) J. Neurosci. 18:9989; and Kaneda et al. (1991) Neuron 6:583-594); a GnRH promoter (see, e.g., Radovick et al. (1991) Proc. Natl. Acad. Sci. USA 88:3402-3406); an L7 promoter (see, e.g., Oberdick et al. (1990) Science 248:223-226); a DNMT promoter (see, e.g., Bartge et al. (1988) Proc. Natl. Acad. Sci. USA 85:3648-3652); an enkephalin promoter (see, e.g., Comb et al. (1988) EMBO J. 17:3793-3805); a myelin basic protein (MBP) promoter; a Ca2+-calmodulin-dependent protein kinase II-alpha (CamKIIα) promoter (see, e.g., Mayford et al. (1996) Proc. Natl. Acad. Sci. USA 93:13250; and Casanova et al. (2001) Genesis 31:37); a CMV enhancer/platelet-derived growth factor-β promoter (see, e.g., Liu et al. (2004) Gene Therapy 11:52-60); and the like.

Adipocyte-specific spatially restricted promoters include, but are not limited to, the aP2 gene promoter/enhancer, e.g., a region from −5.4 kb to +21 bp of a human aP2 gene (see, e.g., Tozzo et al. (1997) Endocrinol. 138:1604; Ross et al. (1990) Proc. Natl. Acad. Sci. USA 87:9590; and Pavjani et al. (2005) Nat. Med. 11:797); a glucose transporter-4 (GLUT4) promoter (see, e.g., Knight et al. (2003) Proc. Natl. Acad. Sci. USA 100:14725); a fatty acid translocase (FAT/CD36) promoter (see, e.g., Kuriki et al. (2002) Biol. Pharm. Bull. 25:1476; and Sato et al. (2002) J. Biol. Chem. 277:15703); a stearoyl-CoA desaturase-1 (SCD1) promoter (Tabor et al. (1999) J. Biol. Chem. 274:20603); a leptin promoter (see, e.g., Mason et al. (1998) Endocrinol. 139:1013; and Chen et al. (1999) Biochem. Biophys. Res. Comm. 262:187); an adiponectin promoter (see, e.g., Kita et al. (2005) Biochem. Biophys. Res. Comm. 331:484; and Chakrabarti

(2010) Endocrinol. 151:2408); an adipsin promoter (see, e.g., Platt et al. (1989) Proc. Natl. Acad. Sci. USA 86:7490); a resistin promoter (see, e.g., Seo et al. (2003) Molec. Endocrinol. 17:1522); and the like.

Cardiomyocyte-specific spatially restricted promoters include, but are not limited to, control sequences derived from the following genes: myosin light chain-2, α-myosin heavy chain, AE3, cardiac troponin C, cardiac actin, and the like. Franz et al. (1997) Cardiovasc. Res. 35:560-566; Robbins et al. (1995) Ann. N.Y. Acad. Sci. 752:492-505; Linn et al. (1995) Circ. Res. 76:584-591; Parmacek et al. (1994) Mol. Cell. Biol. 14:1870-1885; Hunter et al. (1993) Hypertension 22:608-617; and Sartorelli et al. (1992) Proc. Natl. Acad. Sci. USA 89:4047-4051.

Smooth muscle-specific spatially restricted promoters include, but are not limited to, an SM22α promoter (see, e.g., Akyürek et al. (2000) Mol. Med. 6:983; and U.S. Pat. No. 7,169,874); a smoothelin promoter (see, e.g., WO 2001/018048); an α-smooth muscle actin promoter; and the like. For example, a 0.4 kb region of the SM22α promoter, within which lie two CArG elements, has been shown to mediate vascular smooth muscle cell-specific expression (see, e.g., Kim, et al. (1997) Mol. Cell. Biol. 17, 2266-2278; Li, et al., (1996) J. Cell Biol. 132, 849-859; and Moessler, et al. (1996) Development 122, 2415-2425).

Photoreceptor-specific spatially restricted promoters include, but are not limited to, a rhodopsin promoter; a rhodopsin kinase promoter (Young et al. (2003) Ophthalmol. Vis. Sci. 44:4076); a beta phosphodiesterase gene promoter (Nicoud et al. (2007) J. Gene Med. 9:1015); a retinitis pigmentosa gene promoter (Nicoud et al. (2007) supra); an interphotoreceptor retinoid-binding protein (IRBP) gene enhancer (Nicoud et al. (2007) supra); an IRBP gene promoter (Yokoyama et al. (1992) Exp Eye Res. 55:225); and the like.

In some embodiments, a gene modifying system, e.g., DNA encoding a gene modifying polypeptide, DNA encoding a template RNA, or DNA or RNA encoding a heterologous object sequence, is designed such that one or more elements is operably linked to a tissue-specific promoter, e.g., a promoter that is active in T-cells. In further embodiments, the T-cell active promoter is inactive in other cell types, e.g., B-cells, NK cells. In some embodiments, the T-cell active promoter is derived from a promoter for a gene encoding a component of the T-cell receptor, e.g., TRAC, TRBC, TRGC, TRDC. In some embodiments, the T-cell active promoter is derived from a promoter for a gene encoding a component of a T-cell-specific cluster of differentiation protein, e.g., CD3, e.g., CD3D, CD3E, CD3G, CD3Z. In some embodiments, T-

cell-specific promoters in gene modifying systems are discovered by comparing publicly available gene expression data across cell types and selecting promoters from the genes with enhanced expression in T-cells. In some embodiments, promoters may be selecting depending on the desired expression breadth, e.g., promoters that are active in T-cells only, promoters that are active in NK cells only, promoters that are active in both T-cells and NK cells.

Cell-specific promoters known in the art may be used to direct expression of a gene modifying protein, e.g., as described herein. Nonlimiting exemplary mammalian cell-specific promoters have been characterized and used in mice expressing Cre recombinase in a cell-specific manner. Certain nonlimiting exemplary mammalian cell-specific promoters are listed in Table 1 of US9845481, incorporated herein by reference.

In some embodiments, a vector as described herein comprises an expression cassette. Typically, an expression cassette comprises the nucleic acid molecule of the instant invention operatively linked to a promoter sequence. For example, a promoter is operatively linked with a coding sequence when it is capable of affecting the expression of that coding sequence (e.g., the coding sequence is under the transcriptional control of the promoter). Encoding sequences can be operatively linked to regulatory sequences in sense or antisense orientation. In certain embodiments, the promoter is a heterologous promoter. In certain embodiments, an expression cassette may comprise additional elements, for example, an intron, an enhancer, a polyadenylation site, a woodchuck response element (WRE), and/or other elements known to affect expression levels of the encoding sequence. A promoter typically controls the expression of a coding sequence or functional RNA. In certain embodiments, a promoter sequence comprises proximal and more distal upstream elements and can further comprise an enhancer element. An enhancer can typically stimulate promoter activity and may be an innate element of the promoter or a heterologous element inserted to enhance the level or tissue-specificity of a promoter. In certain embodiments, the promoter is derived in its entirety from a native gene. In certain embodiments, the promoter is composed of different elements derived from different naturally occurring promoters. In certain embodiments, the promoter comprises a synthetic nucleotide sequence. It will be understood by those skilled in the art that different promoters will direct the expression of a gene in different tissues or cell types, or at different stages of development, or in response to different environmental conditions or to the presence or the absence of a drug or transcriptional co-factor. Ubiquitous, cell-type-specific, tissue-specific,

developmental stage-specific, and conditional promoters, for example, drug-responsive promoters (e.g., tetracycline-responsive promoters) are well known to those of skill in the art. Exemplary promoters include, but are not limited to, the phosphoglycerate kinase (PKG) promoter, CAG (composite of the CMV enhancer the chicken beta actin promoter (CBA) and the rabbit beta globin intron), NSE (neuronal specific enolase), synapsin or NeuN promoters, the SV40 early promoter, mouse mammary tumor virus LTR promoter; adenovirus major late promoter (Ad MLP), a herpes simplex virus (HSV) promoter, a cytomegalovirus (CMV) promoter such as the CMV immediate early promoter region (CMVIE), SFFV promoter, rous sarcoma virus (RSV) promoter, synthetic promoters, hybrid promoters, and the like. Other promoters can be of human origin or from other species, including from mice. Common promoters include, e.g., the human cytomegalovirus (CMV) immediate early gene promoter, the SV40 early promoter, the Rous sarcoma virus long terminal repeat, [beta]- actin, rat insulin promoter, the phosphoglycerate kinase promoter, the human alpha-1 antitrypsin (hAAT) promoter, the transthyretin promoter, the TBG promoter and other liver-specific promoters, the desmin promoter and similar muscle-specific promoters, the EF1 -alpha promoter, hybrid promoters with multi-tissue specificity, promoters specific for neurons like synapsin and glyceraldehyde-3 -phosphate dehydrogenase promoter, all of which are promoters well known and readily available to those of skill in the art, can be used to obtain high-level expression of the coding sequence of interest. In addition, sequences derived from non-viral genes, such as the murine metallothionein gene, will also find use herein. Such promoter sequences are commercially available from, e.g., Stratagene (San Diego, CA). Additional exemplary promoter sequences are described, for example, in WO2018213786A1 (incorporated by reference herein in its entirety).

In some embodiments, the apolipoprotein E enhancer (ApoE) or a functional fragment thereof is used, e.g., to drive expression in the liver. In some embodiments, two copies of the ApoE enhancer or a functional fragment thereof are used. In some embodiments, the ApoE enhancer or functional fragment thereof is used in combination with a promoter, e.g., the human alpha-1 antitrypsin (hAAT) promoter.

In some embodiments, the regulatory sequences impart tissue-specific gene expression capabilities. In some cases, the tissue-specific regulatory sequences bind tissue-specific transcription factors that induce transcription in a tissue specific manner. Various tissue-specific

regulatory sequences (e.g., promoters, enhancers, etc.) are known in the art. Exemplary tissue-specific regulatory sequences include, but are not limited to, the following tissue-specific promoters: a liver-specific thyroxin binding globulin (TBG) promoter, a insulin promoter, a glucagon promoter, a somatostatin promoter, a pancreatic polypeptide (PPY) promoter, a synapsin-1 (Syn) promoter, a creatine kinase (MCK) promoter, a mammalian desmin (DES) promoter, a α-myosin heavy chain (a-MHC) promoter, or a cardiac Troponin T (cTnT) promoter. Other exemplary promoters include Beta-actin promoter, hepatitis B virus core promoter, Sandig et al., Gene Ther., 3:1002-9 (1996); alpha-fetoprotein (AFP) promoter, Arbuthnot et al., Hum. Gene Ther., 7:1503-14 (1996)), bone osteocalcin promoter (Stein et al., Mol. Biol. Rep., 24:185-96 (1997)); bone sialoprotein promoter (Chen et al., J. Bone Miner. Res., 11:654-64 (1996)), CD2 promoter (Hansal et al., J. Immunol., 161:1063-8 (1998); immunoglobulin heavy chain promoter; T cell receptor α-chain promoter, neuronal such as neuron-specific enolase (NSE) promoter (Andersen et al., Cell. Mol. Neurobiol., 13:503-15 (1993)), neurofilament light-chain gene promoter (Piccioli et al., Proc. Natl. Acad. Sci. USA, 88:5611-5 (1991)), and the neuron-specific vgf gene promoter (Piccioli et al., Neuron, 15:373-84 (1995)), and others. Additional exemplary promoter sequences are described, for example, in U.S. Patent No. 10300146 (incorporated herein by reference in its entirety). In some embodiments, a tissue-specific regulatory element, e.g., a tissue-specific promoter, is selected from one known to be operably linked to a gene that is highly expressed in a given tissue, e.g., as measured by RNA-seq or protein expression data, or a combination thereof. Methods for analyzing tissue specificity by expression are taught in Fagerberg et al. *Mol Cell Proteomics* 13(2):397-406 (2014), which is incorporated herein by reference in its entirety.

In some embodiments, a vector described herein is a multicistronic expression construct. Multicistronic expression constructs include, for example, constructs harboring a first expression cassette, e.g. comprising a first promoter and a first encoding nucleic acid sequence, and a second expression cassette, e.g. comprising a second promoter and a second encoding nucleic acid sequence. Such multicistronic expression constructs may, in some instances, be particularly useful in the delivery of non-translated gene products, such as hairpin RNAs, together with a polypeptide, for example, a gene modifying polypeptide and gene modifying template. In some embodiments, multicistronic expression constructs may exhibit reduced expression levels of one or more of the included transgenes, for example, because of promoter interference or the

presence of incompatible nucleic acid elements in close proximity. If a multicistronic expression construct is part of a viral vector, the presence of a self-complementary nucleic acid sequence may, in some instances, interfere with the formation of structures necessary for viral reproduction or packaging.

In some embodiments, the sequence encodes an RNA with a hairpin. In some embodiments, the hairpin RNA is a guide RNA, a template RNA, a shRNA, or a microRNA. In some embodiments, the first promoter is an RNA polymerase I promoter. In some embodiments, the first promoter is an RNA polymerase II promoter. In some embodiments, the second promoter is an RNA polymerase III promoter. In some embodiments, the second promoter is a U6 or H1 promoter.

Without wishing to be bound by theory, multicistronic expression constructs may not achieve optimal expression levels as compared to expression systems containing only one cistron. One of the suggested causes of lower expression levels achieved with multicistronic expression constructs comprising two or more promoter elements is the phenomenon of promoter interference (see, e.g., Curtin J A, Dane A P, Swanson A, Alexander I E, Ginn S L. *Bidirectional promoter interference between two widely used internal heterologous promoters in a late-generation lentiviral construct*. Gene Ther. 2008 March; 15(5):384-90; and Martin-Duque P, Jezzard S, Kaftansis L, Vassaux G. *Direct comparison of the insulating properties of two genetic elements in an adenoviral vector containing two different expression cassettes.* Hum Gene Ther. 2004 October; 15(10):995-1002; both references incorporated herein by reference for disclosure of promoter interference phenomenon). In some embodiments, the problem of promoter interference may be overcome, e.g., by producing multicistronic expression constructs comprising only one promoter driving transcription of multiple encoding nucleic acid sequences separated by internal ribosomal entry sites, or by separating cistrons comprising their own promoter with transcriptional insulator elements. In some embodiments, single-promoter driven expression of multiple cistrons may result in uneven expression levels of the cistrons. In some embodiments, a promoter cannot efficiently be isolated and isolation elements may not be compatible with some gene transfer vectors, for example, some retroviral vectors.

MicroRNAs

MicroRNAs (miRNAs) and other small interfering nucleic acids generally regulate gene expression via target RNA transcript cleavage/degradation or translational repression of the target messenger RNA (mRNA). miRNAs may, in some instances, be natively expressed, typically as final 19-25 non-translated RNA products. miRNAs generally exhibit their activity through sequence-specific interactions with the 3′ untranslated regions (UTR) of target mRNAs. These endogenously expressed miRNAs may form hairpin precursors that are subsequently processed into an miRNA duplex, and further into a mature single stranded miRNA molecule This mature miRNA generally guides a multiprotein complex, miRISC, which identifies target 3′ UTR regions of target mRNAs based upon their complementarity to the mature miRNA. Useful transgene products may include, for example, miRNAs or miRNA binding sites that regulate the expression of a linked polypeptide. A non-limiting list of miRNA genes; the products of these genes and their homologues are useful as transgenes or as targets for small interfering nucleic acids (e.g., miRNA sponges, antisense oligonucleotides), e.g., in methods such as those listed in US10300146, 22:25-25:48, are herein incorporated by reference. In some embodiments, one or more binding sites for one or more of the foregoing miRNAs are incorporated in a transgene, e.g., a transgene delivered by a rAAV vector, e.g., to inhibit the expression of the transgene in one or more tissues of an animal harboring the transgene. In some embodiments, a binding site may be selected to control the expression of a transgene in a tissue specific manner. For example, binding sites for the liver-specific miR-122 may be incorporated into a transgene to inhibit expression of that transgene in the liver. Additional exemplary miRNA sequences are described, for example, in U.S. Patent No. 10,300,146 (incorporated herein by reference in its entirety).

An miR inhibitor or miRNA inhibitor is generally an agent that blocks miRNA expression and/or processing. Examples of such agents include, but are not limited to, microRNA antagonists, microRNA specific antisense, microRNA sponges, and microRNA oligonucleotides (double-stranded, hairpin, short oligonucleotides) that inhibit miRNA interaction with a Drosha complex. MicroRNA inhibitors, e.g., miRNA sponges, can be expressed in cells from transgenes (e.g., as described in Ebert, M. S. Nature Methods, Epub Aug. 12, 2007; incorporated by reference herein in its entirety). In some embodiments, microRNA sponges, or other miR inhibitors, are used with the AAVs. microRNA sponges generally

specifically inhibit miRNAs through a complementary heptameric seed sequence. In some embodiments, an entire family of miRNAs can be silenced using a single sponge sequence. Other methods for silencing miRNA function (derepression of miRNA targets) in cells will be apparent to one of ordinary skill in the art.

In some embodiments, a gene modifying system, template RNA, or polypeptide described herein is administered to or is active in (e.g., is more active in) a target tissue, e.g., a first tissue. In some embodiments, the gene modifying system, template RNA, or polypeptide is not administered to or is less active in (e.g., not active in) a non-target tissue. In some embodiments, a gene modifying system, template RNA, or polypeptide described herein is useful for modifying DNA in a target tissue, e.g., a first tissue, (e.g., and not modifying DNA in a non-target tissue).

In some embodiments, a gene modifying system comprises (a) a polypeptide described herein or a nucleic acid encoding the same, (b) a template nucleic acid (e.g., template RNA) described herein, and (c) one or more first tissue-specific expression-control sequences specific to the target tissue, wherein the one or more first tissue-specific expression-control sequences specific to the target tissue are in operative association with (a), (b), or (a) and (b), wherein, when associated with (a), (a) comprises a nucleic acid encoding the polypeptide.

In some embodiments, the nucleic acid in (b) comprises RNA.

In some embodiments, the nucleic acid in (b) comprises DNA.

In some embodiments, the nucleic acid in (b): (i) is single-stranded or comprises a single-stranded segment, e.g., is single-stranded DNA or comprises a single-stranded segment and one or more double stranded segments; (ii) has inverted terminal repeats; or (iii) both (i) and (ii).

In some embodiments, the nucleic acid in (b) is double-stranded or comprises a double-stranded segment.

In some embodiments, (a) comprises a nucleic acid encoding the polypeptide.

In some embodiments, the nucleic acid in (a) comprises RNA.

In some embodiments, the nucleic acid in (a) comprises DNA.

In some embodiments, the nucleic acid in (a): (i) is single-stranded or comprises a single-stranded segment, e.g., is single-stranded DNA or comprises a single-stranded segment and one or more double stranded segments; (ii) has inverted terminal repeats; or (iii) both (i) and (ii).

In some embodiments, the nucleic acid in (a) is double-stranded or comprises a double-stranded segment.

In some embodiments, the nucleic acid in (a), (b), or (a) and (b) is linear.

In some embodiments, the nucleic acid in (a), (b), or (a) and (b) is circular, e.g., a plasmid or minicircle.

In some embodiments, the heterologous object sequence is in operative association with a first promoter.

In some embodiments, the one or more first tissue-specific expression-control sequences comprises a tissue specific promoter.

In some embodiments, the tissue-specific promoter comprises a first promoter in operative association with: (i) the heterologous object sequence, (ii) a nucleic acid encoding the retroviral RT, or (iii) (i) and (ii).

In some embodiments, the one or more first tissue-specific expression-control sequences comprises a tissue-specific microRNA recognition sequence in operative association with: (i) the heterologous object sequence, (ii) a nucleic acid encoding the retroviral RT domain, or (iii) (i) and (ii).

In some embodiments, a system comprises a tissue-specific promoter, and the system further comprises one or more tissue-specific microRNA recognition sequences, wherein: (i) the tissue specific promoter is in operative association with: (I) the heterologous object sequence, (II) a nucleic acid encoding the retroviral RT domain, or (III) (I) and (II); and/or (ii) the one or more tissue-specific microRNA recognition sequences are in operative association with: (I) the heterologous object sequence, (II) a nucleic acid encoding the retroviral RT, or (III) (I) and (II).

In some embodiments, wherein (a) comprises a nucleic acid encoding the polypeptide, the nucleic acid comprises a promoter in operative association with the nucleic acid encoding the polypeptide.

In some embodiments, the nucleic acid encoding the polypeptide comprises one or more second tissue-specific expression-control sequences specific to the target tissue in operative association with the polypeptide coding sequence.

In some embodiments, the one or more second tissue-specific expression-control sequences comprises a tissue specific promoter.

In some embodiments, the tissue-specific promoter is the promoter in operative association with the nucleic acid encoding the polypeptide.

In some embodiments, the one or more second tissue-specific expression-control sequences comprises a tissue-specific microRNA recognition sequence.

In some embodiments, the promoter in operative association with the nucleic acid encoding the polypeptide is a tissue-specific promoter, the system further comprising one or more tissue-specific microRNA recognition sequences.

In some embodiments, a nucleic acid component of a system provided by the invention is a sequence (e.g., encoding the polypeptide or comprising a heterologous object sequence) flanked by untranslated regions (UTRs) that modify protein expression levels. Various 5′ and 3′ UTRs can affect protein expression. For example, in some embodiments, the coding sequence may be preceded by a 5′ UTR that modifies RNA stability or protein translation. In some embodiments, the sequence may be followed by a 3′ UTR that modifies RNA stability or translation. In some embodiments, the sequence may be preceded by a 5′ UTR and followed by a 3′ UTR that modify RNA stability or translation. In some embodiments, the 5′ and/or 3′ UTR may be selected from the 5′ and 3′ UTRs of complement factor 3 (C3) (CACTCCTCCCCATCCTCTCCCTCTGTCCCTCTGTCCCTCTGACCCTGCACTGTCCCAG CACC; SEQ ID NO: 11,004) or orosomucoid 1 (ORM1) (CAGGACACAGCCTTGGATCAGGACAGAGACTTGGGGGCCATCCTGCCCCTCCAACC CGACATGTGTACCTCAGCTTTTTCCCTCACTTGCATCAATAAAGCTTCTGTGTTTGGA ACAGCTAA; SEQ ID NO: 11,005) (Asrani et al. RNA Biology 2018). In certain embodiments, the 5′ UTR is the 5′ UTR from C3 and the 3′ UTR is the 3′ UTR from ORM1. In certain embodiments, a 5′ UTR and 3′ UTR for protein expression, e.g., mRNA (or DNA encoding the RNA) for a gene modifying polypeptide or heterologous object sequence, comprise optimized expression sequences. In some embodiments, the 5′ UTR comprises GGGAAAUAAGAGAGAAAAGAAGAGUAAGAAGAAAUAUAAGAGCCACC (SEQ ID NO: 11,006) and/or the 3′ UTR comprising UGAUAAUAGGCUGGAGCCUCGGUGGCCAUGCUUCUUGCCCCUUGGGCCUCCCCCC AGCCCCUCCUCCCCUUCCUGCACCCGUACCCCCGUGGUCUUUGAAUAAAGUCUGA (SEQ ID NO: 11,007), e.g., as described in Richner et al. *Cell* 168(6): P1114-1125 (2017), the sequences of which are incorporated herein by reference.In some embodiments, a 5′ and/or 3′

UTR may be selected to enhance protein expression. In some embodiments, a 5′ and/or 3′ UTR may be selected to modify protein expression such that overproduction inhibition is minimized. In some embodiments, UTRs are around a coding sequence, e.g., outside the coding sequence and in other embodiments proximal to the coding sequence. In some embodiments, additional regulatory elements (e.g., miRNA binding sites, cis-regulatory sites) are included in the UTRs.

In some embodiments, an open reading frame of a gene modifying system, e.g., an ORF of an mRNA (or DNA encoding an mRNA) encoding a gene modifying polypeptide or one or more ORFs of an mRNA (or DNA encoding an mRNA) of a heterologous object sequence, is flanked by a 5′ and/or 3′ untranslated region (UTR) that enhances the expression thereof. In some embodiments, the 5′ UTR of an mRNA component (or transcript produced from a DNA component) of the system comprises the sequence 5′-GGGAAAUAAGAGAGAAAAGAAGAGUAAGAAGAAAUAUAAGAGCCACC-3′; SEQ ID NO: 11,008). In some embodiments, the 3′ UTR of an mRNA component (or transcript produced from a DNA component) of the system comprises the sequence 5′-UGAUAAUAGGCUGGAGCCUCGGUGGCCAUGCUUCUUGCCCCUUGGGCCUCCCCCCAGCCCCUCCUCCCCUUCCUGCACCCGUACCCCCGUGGUCUUUGAAUAAAGUCUGA-3′ (SEQ ID NO: 11,009). This combination of 5′ UTR and 3′ UTR has been shown to result in desirable expression of an operably linked ORF by Richner et al. *Cell* 168(6): P1114-1125 (2017), the teachings and sequences of which are incorporated herein by reference. In some embodiments, a system described herein comprises a DNA encoding a transcript, wherein the DNA comprises the corresponding 5′ UTR and 3′ UTR sequences, with T substituting for U in the above-listed sequence). In some embodiments, a DNA vector used to produce an RNA component of the system further comprises a promoter upstream of the 5′ UTR for initiating *in vitro* transcription, e.g, a T7, T3, or SP6 promoter. The 5′ UTR above begins with GGG, which is a suitable start for optimizing transcription using T7 RNA polymerase. For tuning transcription levels and altering the transcription start site nucleotides to fit alternative 5′ UTRs, the teachings of Davidson et al. *Pac Symp Biocomput* 433-443 (2010) describe T7 promoter variants, and the methods of discovery thereof, that fulfill both of these traits.

Viral vectors and components thereof

Viruses are a useful source of delivery vehicles for the systems described herein, in addition to a source of relevant enzymes or domains as described herein, e.g., as sources of polymerases and polymerase functions used herein, e.g., DNA-dependent DNA polymerase, RNA-dependent RNA polymerase, RNA-dependent DNA polymerase, DNA-dependent RNA polymerase, reverse transcriptase. Some enzymes, e.g., reverse transcriptases, may have multiple activities, e.g., be capable of both RNA-dependent DNA polymerization and DNA-dependent DNA polymerization, e.g., first and second strand synthesis. In some embodiments, the virus used as a gene modifying delivery system or a source of components thereof may be selected from a group as described by Baltimore *Bacteriol Rev* 35(3):235-241 (1971).

In some embodiments, the virus is selected from a Group I virus, e.g., is a DNA virus and packages dsDNA into virions. In some embodiments, the Group I virus is selected from, e.g., Adenoviruses, Herpesviruses, Poxviruses.

In some embodiments, the virus is selected from a Group II virus, e.g., is a DNA virus and packages ssDNA into virions. In some embodiments, the Group II virus is selected from, e.g., Parvoviruses. In some embodiments, the parvovirus is a dependoparvovirus, e.g., an adeno-associated virus (AAV).

In some embodiments, the virus is selected from a Group III virus, e.g., is an RNA virus and packages dsRNA into virions. In some embodiments, the Group III virus is selected from, e.g., Reoviruses. In some embodiments, one or both strands of the dsRNA contained in such virions is a coding molecule able to serve directly as mRNA upon transduction into a host cell, e.g., can be directly translated into protein upon transduction into a host cell without requiring any intervening nucleic acid replication or polymerization steps.

In some embodiments, the virus is selected from a Group IV virus, e.g., is an RNA virus and packages ssRNA(+) into virions. In some embodiments, the Group IV virus is selected from, e.g., Coronaviruses, Picornaviruses, Togaviruses. In some embodiments, the ssRNA(+) contained in such virions is a coding molecule able to serve directly as mRNA upon transduction into a host cell, e.g., can be directly translated into protein upon transduction into a host cell without requiring any intervening nucleic acid replication or polymerization steps.

In some embodiments, the virus is selected from a Group V virus, e.g., is an RNA virus and packages ssRNA(-) into virions. In some embodiments, the Group V virus is selected from, e.g., Orthomyxoviruses, Rhabdoviruses. In some embodiments, an RNA virus with an ssRNA(-)

genome also carries an enzyme inside the virion that is transduced to host cells with the viral genome, e.g., an RNA-dependent RNA polymerase, capable of copying the ssRNA(-) into ssRNA(+) that can be translated directly by the host.

In some embodiments, the virus is selected from a Group VI virus, e.g., is a retrovirus and packages ssRNA(+) into virions. In some embodiments, the Group VI virus is selected from, e.g., retroviruses. In some embodiments, the retrovirus is a lentivirus, e.g., HIV-1, HIV-2, SIV, BIV. In some embodiments, the retrovirus is a spumavirus, e.g., a foamy virus, e.g., HFV, SFV, BFV. In some embodiments, the ssRNA(+) contained in such virions is a coding molecule able to serve directly as mRNA upon transduction into a host cell, e.g., can be directly translated into protein upon transduction into a host cell without requiring any intervening nucleic acid replication or polymerization steps. In some embodiments, the ssRNA(+) is first reverse transcribed and copied to generate a dsDNA genome intermediate from which mRNA can be transcribed in the host cell. In some embodiments, an RNA virus with an ssRNA(+) genome also carries an enzyme inside the virion that is transduced to host cells with the viral genome, e.g., an RNA-dependent DNA polymerase, capable of copying the ssRNA(+) into dsDNA that can be transcribed into mRNA and translated by the host. In some embodiments, the reverse transcriptase from a Group VI retrovirus is incorporated as the reverse transcriptase domain of a gene modifying polypeptide.

In some embodiments, the virus is selected from a Group VII virus, e.g., is a retrovirus and packages dsRNA into virions. In some embodiments, the Group VII virus is selected from, e.g., Hepadnaviruses. In some embodiments, one or both strands of the dsRNA contained in such virions is a coding molecule able to serve directly as mRNA upon transduction into a host cell, e.g., can be directly translated into protein upon transduction into a host cell without requiring any intervening nucleic acid replication or polymerization steps. In some embodiments, one or both strands of the dsRNA contained in such virions is first reverse transcribed and copied to generate a dsDNA genome intermediate from which mRNA can be transcribed in the host cell. In some embodiments, an RNA virus with a dsRNA genome also carries an enzyme inside the virion that is transduced to host cells with the viral genome, e.g., an RNA-dependent DNA polymerase, capable of copying the dsRNA into dsDNA that can be transcribed into mRNA and translated by the host. In some embodiments, the reverse

transcriptase from a Group VII retrovirus is incorporated as the reverse transcriptase domain of a gene modifying polypeptide.

In some embodiments, virions used to deliver nucleic acid in this invention may also carry enzymes involved in the process of gene modification. For example, a retroviral virion may contain a reverse transcriptase domain that is delivered into a host cell along with the nucleic acid. In some embodiments, an RNA template may be associated with a gene modifying polypeptide within a virion, such that both are co-delivered to a target cell upon transduction of the nucleic acid from the viral particle. In some embodiments, the nucleic acid in a virion may comprise DNA, e.g., linear ssDNA, linear dsDNA, circular ssDNA, circular dsDNA, minicircle DNA, dbDNA, ceDNA. In some embodiments, the nucleic acid in a virion may comprise RNA, e.g., linear ssRNA, linear dsRNA, circular ssRNA, circular dsRNA. In some embodiments, a viral genome may circularize upon transduction into a host cell, e.g., a linear ssRNA molecule may undergo a covalent linkage to form a circular ssRNA, a linear dsRNA molecule may undergo a covalent linkage to form a circular dsRNA or one or more circular ssRNA. In some embodiments, a viral genome may replicate by rolling circle replication in a host cell. In some embodiments, a viral genome may comprise a single nucleic acid molecule, e.g., comprise a non-segmented genome. In some embodiments, a viral genome may comprise two or more nucleic acid molecules, e.g., comprise a segmented genome. In some embodiments, a nucleic acid in a virion may be associated with one or proteins. In some embodiments, one or more proteins in a virion may be delivered to a host cell upon transduction. In some embodiments, a natural virus may be adapted for nucleic acid delivery by the addition of virion packaging signals to the target nucleic acid, wherein a host cell is used to package the target nucleic acid containing the packaging signals.

In some embodiments, a virion used as a delivery vehicle may comprise a commensal human virus. In some embodiments, a virion used as a delivery vehicle may comprise an anellovirus, the use of which is described in WO2018232017A1, which is incorporated herein by reference in its entirety.

AAV Administration

In some embodiments, an adeno-associated virus (AAV) is used in conjunction with the system, template nucleic acid, and/or polypeptide described herein. In some embodiments, an

AAV is used to deliver, administer, or package the system, template nucleic acid, and/or polypeptide described herein. In some embodiments, the AAV is a recombinant AAV (rAAV).

In some embodiments, a system comprises (a) a polypeptide described herein or a nucleic acid encoding the same, (b) a template nucleic acid (e.g., template RNA) described herein, and (c) one or more first tissue-specific expression-control sequences specific to the target tissue, wherein the one or more first tissue-specific expression-control sequences specific to the target tissue are in operative association with (a), (b), or (a) and (b), wherein, when associated with (a), (a) comprises a nucleic acid encoding the polypeptide.

In some embodiments, a system described herein further comprises a first recombinant adeno-associated virus (rAAV) capsid protein; wherein the at least one of (a) or (b) is associated with the first rAAV capsid protein, wherein at least one of (a) or (b) is flanked by AAV inverted terminal repeats (ITRs).

In some embodiments, (a) and (b) are associated with the first rAAV capsid protein.

In some embodiments, (a) and (b) are on a single nucleic acid.

In some embodiments, the system further comprises a second rAAV capsid protein, wherein at least one of (a) or (b) is associated with the second rAAV capsid protein, and wherein the at least one of (a) or (b) associated with the second rAAV capsid protein is different from the at least one of (a) or (b) is associated with the first rAAV capsid protein.

In some embodiments, the at least one of (a) or (b) is associated with the first or second rAAV capsid protein is dispersed in the interior of the first or second rAAV capsid protein, which first or second rAAV capsid protein is in the form of an AAV capsid particle.

In some embodiments, the system further comprises a nanoparticle, wherein the nanoparticle is associated with at least one of (a) or (b).

In some embodiments, (a) and (b), respectively are associated with: a) a first rAAV capsid protein and a second rAAV capsid protein; b) a nanoparticle and a first rAAV capsid protein; c) a first rAAV capsid protein; d) a first adenovirus capsid protein; e) a first nanoparticle and a second nanoparticle; or f) a first nanoparticle.

Viral vectors are useful for delivering all or part of a system provided by the invention, e.g., for use in methods provided by the invention. Systems derived from different viruses have been employed for the delivery of polypeptides or nucleic acids; for example: integrase-deficient lentivirus, adenovirus, adeno-associated virus (AAV), herpes simplex virus, and baculovirus

(reviewed in Hodge et al. Hum Gene Ther 2017; Narayanavari et al. Crit Rev Biochem Mol Biol 2017; Boehme et al. Curr Gene Ther 2015).

Adenoviruses are common viruses that have been used as gene delivery vehicles given well-defined biology, genetic stability, high transduction efficiency, and ease of large-scale production (see, for example, review by Lee et al. Genes & Diseases 2017). They possess linear dsDNA genomes and come in a variety of serotypes that differ in tissue and cell tropisms. In order to prevent replication of infectious virus in recipient cells, adenovirus genomes used for packaging are deleted of some or all endogenous viral proteins, which are provided in trans in viral production cells. This renders the genomes helper-dependent, meaning they can only be replicated and packaged into viral particles in the presence of the missing components provided by so-called helper functions. A helper-dependent adenovirus system with all viral ORFs removed may be compatible with packaging foreign DNA of up to ~37 kb (Parks et al. J Virol 1997). In some embodiments, an adenoviral vector is used to deliver DNA corresponding to the polypeptide or template component of the gene modifying system, or both are contained on separate or the same adenoviral vector. In some embodiments, the adenovirus is a helper-dependent adenovirus (HD-AdV) that is incapable of self-packaging. In some embodiments, the adenovirus is a high-capacity adenovirus (HC-AdV) that has had all or a substantial portion of endogenous viral ORFs deleted, while retaining the necessary sequence components for packaging into adenoviral particles. For this type of vector, the only adenoviral sequences required for genome packaging are noncoding sequences: the inverted terminal repeats (ITRs) at both ends and the packaging signal at the 5′-end (Jager et al. Nat Protoc 2009). In some embodiments, the adenoviral genome also comprises stuffer DNA to meet a minimal genome size for optimal production and stability (see, for example, Hausl et al. Mol Ther 2010). In some embodiments, an adenovirus is used to deliver a gene modifying system to the liver.

In some embodiments, an adenovirus is used to deliver a gene modifying system to HSCs, e.g., HDAd5/35++. HDAd5/35++ is an adenovirus with modified serotype 35 fibers that de-target the vector from the liver (Wang et al. Blood Adv 2019). In some embodiments, the adenovirus that delivers a gene modifying system to HSCs utilizes a receptor that is expressed specifically on primitive HSCs, e.g., CD46.

Adeno-associated viruses (AAV) belong to the parvoviridae family and more specifically constitute the dependoparvovirus genus. The AAV genome is composed of a linear single-

stranded DNA molecule which contains approximately 4.7 kilobases (kb) and consists of two major open reading frames (ORFs) encoding the non-structural Rep (replication) and structural Cap (capsid) proteins. A second ORF within the cap gene was identified that encodes the assembly-activating protein (AAP). The DNAs flanking the AAV coding regions are two cis-acting inverted terminal repeat (ITR) sequences, approximately 145 nucleotides in length, with interrupted palindromic sequences that can be folded into energetically stable hairpin structures that function as primers of DNA replication. In addition to their role in DNA replication, the ITR sequences have been shown to be involved in viral DNA integration into the cellular genome, rescue from the host genome or plasmid, and encapsidation of viral nucleic acid into mature virions (Muzyczka, (1992) Curr. Top. Micro. Immunol. 158:97-129). In some embodiments, one or more gene modifying nucleic acid components is flanked by ITRs derived from AAV for viral packaging. See, e.g., WO2019113310.

In some embodiments, one or more components of the gene modifying system are carried via at least one AAV vector. In some embodiments, the at least one AAV vector is selected for tropism to a particular cell, tissue, organism. In some embodiments, the AAV vector is pseudotyped, e.g., AAV2/8, wherein AAV2 describes the design of the construct but the capsid protein is replaced by that from AAV8. It is understood that any of the described vectors could be pseudotype derivatives, wherein the capsid protein used to package the AAV genome is derived from that of a different AAV serotype. Without wishing to be limited in vector choice, a list of exemplary AAV serotypes can be found in Table 18. In some embodiments, an AAV to be employed for gene modifying may be evolved for novel cell or tissue tropism as has been demonstrated in the literature (e.g., Davidsson et al. Proc Natl Acad Sci U S A 2019).

In some embodiments, the AAV delivery vector is a vector which has two AAV inverted terminal repeats (ITRs) and a nucleotide sequence of interest (for example, a sequence coding for a gene modifying polypeptideor a DNA template, or both), each of said ITRs having an interrupted (or noncontiguous) palindromic sequence, i.e., a sequence composed of three segments: a first segment and a last segment that are identical when read 5'→ 3' but hybridize when placed against each other, and a segment that is different that separates the identical segments. See, for example, WO2012123430.

Conventionally, AAV virions with capsids are produced by introducing a plasmid or plasmids encoding the rAAV or scAAV genome, Rep proteins, and Cap proteins (Grimm et al,

1998). Upon introduction of these helper plasmids in trans, the AAV genome is "rescued" (i.e., released and subsequently recovered) from the host genome, and is further encapsidated to produce infectious AAV. In some embodiments, one or more gene modifying nucleic acids are packaged into AAV particles by introducing the ITR-flanked nucleic acids into a packaging cell in conjunction with the helper functions.

In some embodiments, the AAV genome is a so called self-complementary genome (referred to as scAAV), such that the sequence located between the ITRs contains both the desired nucleic acid sequence (e.g., DNA encoding the gene modifying polypeptide or template, or both) in addition to the reverse complement of the desired nucleic acid sequence, such that these two components can fold over and self-hybridize. In some embodiments, the self-complementary modules are separated by an intervening sequence that permits the DNA to fold back on itself, e.g., forms a stem-loop. An scAAV has the advantage of being poised for transcription upon entering the nucleus, rather than being first dependent on ITR priming and second-strand synthesis to form dsDNA. In some embodiments, one or more gene modifying components is designed as an scAAV, wherein the sequence between the AAV ITRs contains two reverse complementing modules that can self-hybridize to create dsDNA.

In some embodiments, nucleic acid (e.g., encoding a polypeptide, or a template, or both) delivered to cells is closed-ended, linear duplex DNA (CELiD DNA or ceDNA). In some embodiments, ceDNA is derived from the replicative form of the AAV genome (Li et al. PLoS One 2013). In some embodiments, the nucleic acid (e.g., encoding a polypeptide, or a template DNA, or both) is flanked by ITRs, e.g., AAV ITRs, wherein at least one of the ITRs comprises a terminal resolution site and a replication protein binding site (sometimes referred to as a replicative protein binding site). In some embodiments, the ITRs are derived from an adeno-associated virus, e.g., AAV1, AAV2, AAV3, AAV4, AAV5, AAV6, AAV7, AAV8, AAV9, AAV10, AAV11, AAV12, or a combination thereof. In some embodiments, the ITRs are symmetric. In some embodiments, the ITRs are asymmetric. In some embodiments, at least one Rep protein is provided to enable replication of the construct. In some embodiments, the at least one Rep protein is derived from an adeno-associated virus, e.g., AAV1, AAV2, AAV3, AAV4, AAV5, AAV6, AAV7, AAV8, AAV9, AAV10, AAV11, AAV12, or a combination thereof. In some embodiments, ceDNA is generated by providing a production cell with (i) DNA flanked by

ITRs, e.g., AAV ITRs, and (ii) components required for ITR-dependent replication, e.g., AAV proteins Rep78 and Rep52 (or nucleic acid encoding the proteins). In some embodiments, ceDNA is free of any capsid protein, e.g., is not packaged into an infectious AAV particle. In some embodiments, ceDNA is formulated into LNPs (see, for example, WO2019051289A1).

In some embodiments, the ceDNA vector consists of two self-complementary sequences, e.g., asymmetrical or symmetrical or substantially symmetrical ITRs as defined herein, flanking said expression cassette, wherein the ceDNA vector is not associated with a capsid protein. In some embodiments, the ceDNA vector comprises two self-complementary sequences found in an AAV genome, where at least one ITR comprises an operative Rep-binding element (RBE) (also sometimes referred to herein as "RBS") and a terminal resolution site (trs) of AAV or a functional variant of the RBE. See, for example, WO2019113310.

In some embodiments, the AAV genome comprises two genes that encode four replication proteins and three capsid proteins, respectively. In some embodiments, the genes are flanked on either side by 145-bp inverted terminal repeats (ITRs). In some embodiments, the virion comprises up to three capsid proteins (Vp1, Vp2, and/or Vp3), e.g., produced in a 1:1:10 ratio. In some embodiments, the capsid proteins are produced from the same open reading frame and/or from differential splicing (Vp1) and alternative translational start sites (Vp2 and Vp3, respectively). Generally, Vp3 is the most abundant subunit in the virion and participates in receptor recognition at the cell surface defining the tropism of the virus. In some embodiments, Vp1 comprises a phospholipase domain, e.g., which functions in viral infectivity, in the N-terminus of Vp1.

In some embodiments, packaging capacity of the viral vectors limits the size of the gene modifying system that can be packaged into the vector. For example, the packaging capacity of the AAVs can be about 4.5 kb (e.g., about 3.0, 3.5, 4.0, 4.5, 5.0, 5.5, or 6.0 kb), e.g., including one or two inverted terminal repeats (ITRs), e.g., 145 base ITRs.

In some embodiments, recombinant AAV (rAAV) comprises cis-acting 145-bp ITRs flanking vector transgene cassettes, e.g., providing up to 4.5 kb for packaging of foreign DNA. Subsequent to infection, rAAV can, in some instances, express a fusion protein of the invention and persist without integration into the host genome by existing episomally in circular head-to-tail concatemers. rAAV can be used, for example, *in vitro* and *in vivo*. In some embodiments,

AAV-mediated gene delivery requires that the length of the coding sequence of the gene is equal or greater in size than the wild-type AAV genome.

AAV delivery of genes that exceed this size and/or the use of large physiological regulatory elements can be accomplished, for example, by dividing the protein(s) to be delivered into two or more fragments. In some embodiments, the N-terminal fragment is fused to an intein-N sequence. In some embodiments, the C- terminal fragment is fused to an intein-C sequence. In embodiments, the fragments are packaged into two or more AAV vectors.

In some embodiments, dual AAV vectors are generated by splitting a large transgene expression cassette in two separate halves (5′ and 3′ ends, or head and tail), e.g., wherein each half of the cassette is packaged in a single AAV vector (of <5 kb). The re-assembly of the full-length transgene expression cassette can, in some embodiments, then be achieved upon co-infection of the same cell by both dual AAV vectors. In some embodiments, co-infection is followed by one or more of: (1) homologous recombination (HR) between 5′ and 3′ genomes (dual AAV overlapping vectors); (2) ITR-mediated tail-to-head concatemerization of 5′ and 3′ genomes (dual AAV trans-splicing vectors); and/or (3) a combination of these two mechanisms (dual AAV hybrid vectors). In some embodiments, the use of dual AAV vectors *in vivo* results in the expression of full-length proteins. In some embodiments, the use of the dual AAV vector platform represents an efficient and viable gene transfer strategy for transgenes of greater than about 4.0, 4.1, 4.2, 4.3, 4.4, 4.5, 4.6, 4.7, 4.8, 4.9, or 5.0 kb in size. In some embodiments, AAV vectors can also be used to transduce cells with target nucleic acids, e.g., in the *in vitro* production of nucleic acids and peptides. In some embodiments, AAV vectors can be used for *in vivo* and *ex vivo* gene therapy procedures (see, e.g., West et al., Virology 160:38-47 (1987); U.S. Patent No. 4,797,368; WO 93/24641; Kotin, Human Gene Therapy 5:793-801 (1994); Muzyczka, J. Clin. Invest.94:1351 (1994); each of which is incorporated herein by reference in their entirety). The construction of recombinant AAV vectors is described in a number of publications, including U.S. Patent No.5,173,414; Tratschin et al., Mol. Cell. Biol.5:3251- 3260 (1985); Tratschin, et al., Mol. Cell. Biol.4:2072-2081 (1984); Hermonat & Muzyczka, PNAS 81:6466-6470 (1984); and Samulski et al., J. Virol.63:03822-3828 (1989) (incorporated by reference herein in their entirety).

In some embodiments, a gene modifying polypeptide described herein (e.g., with or without one or more guide nucleic acids) can be delivered using AAV, lentivirus, adenovirus or

other plasmid or viral vector types, in particular, using formulations and doses from, for example, U.S. Patent No. 8,454,972 (formulations, doses for adenovirus), U.S. Patent No.8,404,658 (formulations, doses for AAV) and U.S. Patent No.5,846,946 (formulations, doses for DNA plasmids) and from clinical trials and publications regarding the clinical trials involving lentivirus, AAV and adenovirus. For example, for AAV, the route of administration, formulation and dose can be as described in U.S. Patent No.8,454,972 and as in clinical trials involving AAV. For adenovirus, the route of administration, formulation and dose can be as described in U.S. Patent No.8,404,658 and as in clinical trials involving adenovirus. For plasmid delivery, the route of administration, formulation and dose can be as described in U.S. Patent No.5,846,946 and as in clinical studies involving plasmids. Doses can be based on or extrapolated to an average 70 kg individual (e.g. a male adult human), and can be adjusted for patients, subjects, mammals of different weight and species. Frequency of administration is within the ambit of the medical or veterinary practitioner (e.g., physician, veterinarian), depending on usual factors including the age, sex, general health, other conditions of the patient or subject and the particular condition or symptoms being addressed. In some embodiments, the viral vectors can be injected into the tissue of interest. For cell-type specific gene modifying, the expression of the gene modifying polypeptide and optional guide nucleic acid can, in some embodiments, be driven by a cell-type specific promoter.

In some embodiments, AAV allows for low toxicity, for example, due to the purification method not requiring ultracentrifugation of cell particles that can activate the immune response. In some embodiments, AAV allows low probability of causing insertional mutagenesis, for example, because it does not substantially integrate into the host genome.

In some embodiments, AAV has a packaging limit of about 4.4, 4.5, 4.6, 4.7, or 4.75 kb. In some embodiments, a gene modifying polypeptide-encoding sequence, promoter, and transcription terminator can fit into a single viral vector. SpCas9 (4.1 kb) may, in some instances, be difficult to package into AAV. Therefore, in some embodiments, a gene modifying polypeptide coding sequence is used that is shorter in length than other gene modifying polypeptide coding sequences or base editors. In some embodiments, the gene modifying polypeptide encoding sequences are less than about 4.5 kb, 4.4 kb, 4.3 kb, 4.2 kb, 4.1 kb, 4 kb, 3.9 kb, 3.8 kb, 3.7 kb, 3.6 kb, 3.5 kb, 3.4 kb, 3.3 kb, 3.2 kb, 3.1 kb, 3 kb, 2.9 kb, 2.8 kb, 2.7 kb, 2.6 kb, 2.5 kb, 2 kb, or 1.5 kb.

An AAV can be AAV1, AAV2, AAV5 or any combination thereof. In some embodiments, the type of AAV is selected with respect to the cells to be targeted; e.g., AAV serotypes 1, 2, 5 or a hybrid capsid AAV1, AAV2, AAV5 or any combination thereof can be selected for targeting brain or neuronal cells; or AAV4 can be selected for targeting cardiac tissue. In some embodiments, AAV8 is selected for delivery to the liver. Exemplary AAV serotypes as to these cells are described, for example, in Grimm, D. et al, J. Virol.82: 5887-5911 (2008) (incorporated herein by reference in its entirety). In some embodiments, AAV refers all serotypes, subtypes, and naturally-occurring AAV as well as recombinant AAV. AAV may be used to refer to the virus itself or a derivative thereof. In some embodiments, AAV includes AAV1, AAV2, AAV3, AAV3B, AAV4, AAV5, AAV6, AAV6.2, AAV7, AAVrh.64Rl, AAVhu.37, AAVrh.8, AAVrh.32.33, AAV8, AAV9, AAV-DJ, AAV2/8, AAVrhlO, AAVLK03, AV10, AAV11, AAV 12, rhlO, and hybrids thereof, avian AAV, bovine AAV, canine AAV, equine AAV, primate AAV, non-primate AAV, and ovine AAV. The genomic sequences of various serotypes of AAV, as well as the sequences of the native terminal repeats (TRs), Rep proteins, and capsid subunits are known in the art. Such sequences may be found in the literature or in public databases such as GenBank. Additional exemplary AAV serotypes are listed in Table 18.

Table 18. Exemplary AAV serotypes.

In some embodiments, a pharmaceutical composition (e.g., comprising an AAV as described herein) has less than 10% empty capsids, less than 8% empty capsids, less than 7% empty capsids, less than 5% empty capsids, less than 3% empty capsids, or less than 1 % empty capsids. In some embodiments, the pharmaceutical composition has less than about 5% empty capsids. In some embodiments, the number of empty capsids is below the limit of detection. In some embodiments, it is advantageous for the pharmaceutical composition to have low amounts of empty capsids, e.g., because empty capsids may generate an adverse response (e.g., immune response, inflammatory response, liver response, and/or cardiac response), e.g., with little or no substantial therapeutic benefit.

In some embodiments, the residual host cell protein (rHCP) in the pharmaceutical composition is less than or equal to 100 ng/ml rHCP per 1 x 10^{13} vg/ml, e.g., less than or equal to

40 ng/ml rHCP per 1 x 10^{13} vg/ml or 1-50 ng/ml rHCP per 1 x 10^{13} vg/ml. In some embodiments, the pharmaceutical composition comprises less than 10 ng rHCP per l.0 x 10^{13} vg, or less than 5 ng rHCP per 1.0 x 10^{13} vg, less than 4 ng rHCP per 1.0 x 10^{13} vg, or less than 3 ng rHCP per 1.0 x 10^{13} vg, or any concentration in between. In some embodiments, the residual host cell DNA (hcDNA) in the pharmaceutical composition is less than or equal to 5 x 10^{6} pg/ml hcDNA per 1 x 10^{13} vg/ml, less than or equal to 1.2 x 10^{6} pg/ml hcDNA per 1 x 10^{13} vg/ml, or 1 x 10^{5} pg/ml hcDNA per 1 x 10^{13} vg/ml. In some embodiments, the residual host cell DNA in said pharmaceutical composition is less than 5.0 x 10^{5} pg per 1 x 10^{13} vg, less than 2.0 x 10^{5} pg per l.0 x 10^{13} vg, less than 1.1 x 10^{5} pg per 1.0 x 10^{13} vg, less than 1.0 x 10^{5} pg hcDNA per 1.0 x 10^{13} vg, less than 0.9 x 10^{5} pg hcDNA per 1.0 x 10^{13} vg, less than 0.8 x 10^{5} pg hcDNA per 1.0 x 10^{13} vg, or any concentration in between.

In some embodiments, the residual plasmid DNA in the pharmaceutical composition is less than or equal to 1.7 x 10^{5} pg/ml per 1.0 x 10^{13} vg/ml, or 1 x 10^{5} pg/ml per 1 x 1.0 x 10^{13} vg/ml, or 1.7 x 10^{6} pg/ml per 1.0 x 10^{13} vg/ml. In some embodiments, the residual DNA plasmid in the pharmaceutical composition is less than 10.0 x 10^{5} pg by 1.0 x 10^{13} vg, less than 8.0 x 10^{5} pg by 1.0 x 10^{13} vg or less than 6.8 x 10^{5} pg by 1.0 x 10^{13} vg. In embodiments, the pharmaceutical composition comprises less than 0.5 ng per 1.0 x 10^{13} vg, less than 0.3 ng per 1.0 x 10^{13} vg, less than 0.22 ng per 1.0 x 10^{13} vg or less than 0.2 ng per 1.0 x 10^{13} vg or any intermediate concentration of bovine serum albumin (BSA). In embodiments, the benzonase in the pharmaceutical composition is less than 0.2 ng by 1.0 x 10^{13} vg, less than 0.1 ng by 1.0 x 10^{13} vg, less than 0.09 ng by 1.0 x 10^{13} vg, less than 0.08 ng by 1.0 x 10^{13} vg or any intermediate concentration. In embodiments, Poloxamer 188 in the pharmaceutical composition is about 10 to 150 ppm, about 15 to 100 ppm or about 20 to 80 ppm. In embodiments, the cesium in the pharmaceutical composition is less than 50 pg / g (ppm), less than 30 pg / g (ppm) or less than 20 pg / g (ppm) or any intermediate concentration.

In embodiments, the pharmaceutical composition comprises total impurities, e.g., as determined by SDS-PAGE, of less than 10%, less than 8%, less than 7%, less than 6%, less than 5%, less than 4%, less than 3%, less than 2%, or any percentage in between. In embodiments, the total purity, e.g., as determined by SDS-PAGE, is greater than 90%, greater than 92%, greater than 93%, greater than 94%, greater than 95%, greater than 96%, greater than 97%, greater than 98%, or any percentage in between. In embodiments, no single unnamed related impurity, e.g.,

as measured by SDS-PAGE, is greater than 5%, greater than 4%, greater than 3% or greater than 2%, or any percentage in between. In embodiments, the pharmaceutical composition comprises a percentage of filled capsids relative to total capsids (e.g., peak 1 + peak 2 as measured by analytical ultracentrifugation) of greater than 85%, greater than 86%, greater than 87%, greater than 88%, greater than 89%, greater than 90%, greater than 91%, greater than 91.9%, greater than 92%, greater than 93%, or any percentage in between. In embodiments of the pharmaceutical composition, the percentage of filled capsids measured in peak 1 by analytical ultracentrifugation is 20-80%, 25-75%, 30-75%, 35-75%, or 37.4-70.3%. In embodiments of the pharmaceutical composition, the percentage of filled capsids measured in peak 2 by analytical ultracentrifugation is 20-80%, 20-70%, 22-65%, 24-62%, or 24.9-60.1%.

In one embodiment, the pharmaceutical composition comprises a genomic titer of 1.0 to 5.0 x 10^{13} vg / mL, 1.2 to 3.0 x 10^{13} vg / mL or 1.7 to 2.3 x 10^{13} vg / ml. In one embodiment, the pharmaceutical composition exhibits a biological load of less than 5 CFU / mL, less than 4 CFU / mL, less than 3 CFU / mL, less than 2 CFU / mL or less than 1 CFU / mL or any intermediate contraction. In embodiments, the amount of endotoxin according to USP, for example, USP <85> (incorporated by reference in its entirety) is less than 1.0 EU / mL, less than 0.8 EU / mL or less than 0.75 EU / mL. In embodiments, the osmolarity of a pharmaceutical composition according to USP, for example, USP <785> (incorporated by reference in its entirety) is 350 to 450 mOsm / kg, 370 to 440 mOsm / kg or 390 to 430 mOsm / kg. In embodiments, the pharmaceutical composition contains less than 1200 particles that are greater than 25 μm per container, less than 1000 particles that are greater than 25 μm per container, less than 500 particles that are greater than 25 μm per container or any intermediate value. In embodiments, the pharmaceutical composition contains less than 10,000 particles that are greater than 10 μm per container, less than 8000 particles that are greater than 10 μm per container or less than 600 particles that are greater than 10 pm per container.

In one embodiment, the pharmaceutical composition has a genomic titer of 0.5 to 5.0 x 10^{13} vg / mL, 1.0 to 4.0 x 10^{13} vg / mL, 1.5 to 3.0 x 10^{13} vg / ml or 1.7 to 2.3 x 10^{13} vg / ml. In one embodiment, the pharmaceutical composition described herein comprises one or more of the following: less than about 0.09 ng benzonase per 1.0 x 10^{13} vg, less than about 30 pg / g (ppm) of cesium, about 20 to 80 ppm Poloxamer 188, less than about 0.22 ng BSA per 1.0 x 10^{13} vg, less than about 6.8 x 10^{5} pg of residual DNA plasmid per 1.0 x 10^{13} vg, less than about 1.1 x

10^{5} pg of residual hcDNA per 1.0 x 10^{13} vg, less than about 4 ng of rHCP per 1.0 x 10^{13} vg, pH 7.7 to 8.3, about 390 to 430 mOsm / kg, less than about 600 particles that are > 25 μm in size per container, less than about 6000 particles that are > 10 μm in size per container, about 1.7 x 10^{13} - 2.3 x 10^{13} vg / mL genomic titer, infectious titer of about 3.9 x 10^{8} to 8.4 x 10^{10} IU per 1.0 x 10^{13} vg, total protein of about 100-300 pg per 1.0 x 10^{13} vg, mean survival of >24 days in A7SMA mice with about 7.5 x 10^{13} vg / kg dose of viral vector, about 70 to 130% relative potency based on an *in vitro* cell based assay and / or less than about 5% empty capsid. In various embodiments, the pharmaceutical compositions described herein comprise any of the viral particles discussed here, retain a potency of between ± 20%, between ± 15%, between ± 10% or within ± 5% of a reference standard. In some embodiments, potency is measured using a suitable *in vitro* cell assay or *in vivo* animal model.

Additional methods of preparation, characterization, and dosing AAV particles are taught in WO2019094253, which is incorporated herein by reference in its entirety.

Additional rAAV constructs that can be employed consonant with the invention include those described in Wang et al 2019, available at: //doi.org/10.1038/s41573-019-0012-9, including Table 1 thereof, which is incorporated by reference in its entirety.

Lipid Nanoparticles

The methods and systems provided herein may employ any suitable carrier or delivery modality, including, in certain embodiments, lipid nanoparticles (LNPs). Lipid nanoparticles, in some embodiments, comprise one or more ionic lipids, such as non-cationic lipids (e.g., neutral or anionic, or zwitterionic lipids); one or more conjugated lipids (such as PEG-conjugated lipids or lipids conjugated to polymers described in Table 5 of WO2019217941; incorporated herein by reference in its entirety); one or more sterols (e.g., cholesterol); and, optionally, one or more targeting molecules (e.g., conjugated receptors, receptor ligands, antibodies); or combinations of the foregoing.

Lipids that can be used in nanoparticle formations (e.g., lipid nanoparticles) include, for example those described in Table 4 of WO2019217941, which is incorporated by reference—e.g., a lipid-containing nanoparticle can comprise one or more of the lipids in Table 4 of WO2019217941. Lipid nanoparticles can include additional elements, such as polymers, such as the polymers described in Table 5 of WO2019217941, incorporated by reference.

In some embodiments, conjugated lipids, when present, can include one or more of PEG-diacylglycerol (DAG) (such as l-(monomethoxy-polyethyleneglycol)-2,3- dimyristoylglycerol (PEG-DMG)), PEG-dialkyloxypropyl (DAA), PEG-phospholipid, PEG- ceramide (Cer), a pegylated phosphatidylethanoloamine (PEG-PE), PEG succinate diacylglycerol (PEGS-DAG) (such as 4-0-(2',3'-di(tetradecanoyloxy)propyl-l-0-(w- methoxy(polyethoxy)ethyl) butanedioate (PEG-S-DMG)), PEG dialkoxypropylcarbam, N- (carbonyl-methoxypoly ethylene glycol 2000)-1 ,2-distearoyl-sn-glycero-3-phosphoethanolamine sodium salt, and those described in Table 2 of WO2019051289 (incorporated by reference), and combinations of the foregoing.

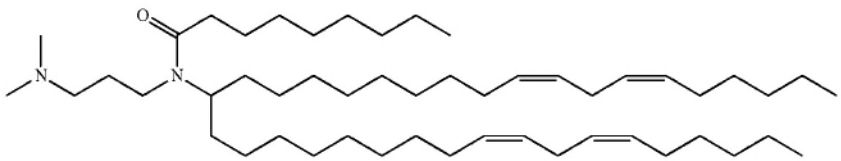
In some embodiments, sterols that can be incorporated into lipid nanoparticles include one or more of cholesterol or cholesterol derivatives, such as those in W02009/127060 or US2010/0130588, which are incorporated by reference. Additional exemplary sterols include phytosterols, including those described in Eygeris et al (2020), dx.doi.org/10.1021/acs.nanolett.0c01386, incorporated herein by reference.

In some embodiments, the lipid particle comprises an ionizable lipid, a non-cationic lipid, a conjugated lipid that inhibits aggregation of particles, and a sterol. The amounts of these components can be varied independently and to achieve desired properties. For example, in some embodiments, the lipid nanoparticle comprises an ionizable lipid is in an amount from about 20 mol % to about 90 mol % of the total lipids (in other embodiments it may be 20-70% (mol), 30-60% (mol) or 40-50% (mol); about 50 mol % to about 90 mol % of the total lipid present in the lipid nanoparticle), a non-cationic lipid in an amount from about 5 mol % to about 30 mol % of the total lipids, a conjugated lipid in an amount from about 0.5 mol % to about 20 mol % of the total lipids, and a sterol in an amount from about 20 mol % to about 50 mol % of the total lipids. The ratio of total lipid to nucleic acid (e.g., encoding the gene modifying polypeptide or template nucleic acid) can be varied as desired. For example, the total lipid to nucleic acid (mass or weight) ratio can be from about 10: 1 to about 30: 1.

In some embodiments, an ionizable lipid may be a cationic lipid, an ionizable cationic lipid, e.g., a cationic lipid that can exist in a positively charged or neutral form depending on pH, or an amine-containing lipid that can be readily protonated. In some embodiments, the cationic lipid is a lipid capable of being positively charged, e.g., under physiological conditions. Exemplary cationic lipids include one or more amine group(s) which bear the positive charge. In some embodiments, the lipid particle comprises a cationic lipid in formulation with one or more

of neutral lipids, ionizable amine-containing lipids, biodegradable alkyn lipids, steroids, phospholipids including polyunsaturated lipids, structural lipids (e.g., sterols), PEG, cholesterol and polymer conjugated lipids. In some embodiments, the cationic lipid may be an ionizable cationic lipid. An exemplary cationic lipid as disclosed herein may have an effective pKa over 6.0. In embodiments, a lipid nanoparticle may comprise a second cationic lipid having a different effective pKa (e.g., greater than the first effective pKa), than the first cationic lipid. A lipid nanoparticle may comprise between 40 and 60 mol percent of a cationic lipid, a neutral lipid, a steroid, a polymer conjugated lipid, and a therapeutic agent, e.g., a nucleic acid (e.g., RNA) described herein (e.g., a template nucleic acid or a nucleic acid encoding a gene modifying polypeptide), encapsulated within or associated with the lipid nanoparticle. In some embodiments, the nucleic acid is co-formulated with the cationic lipid. The nucleic acid may be adsorbed to the surface of an LNP, e.g., an LNP comprising a cationic lipid. In some embodiments, the nucleic acid may be encapsulated in an LNP, e.g., an LNP comprising a cationic lipid. In some embodiments, the lipid nanoparticle may comprise a targeting moiety, e.g., coated with a targeting agent. In embodiments, the LNP formulation is biodegradable. In some embodiments, a lipid nanoparticle comprising one or more lipid described herein, e.g., Formula (i), (ii), (ii), (vii) and/or (ix) encapsulates at least 1%, at least 5%, at least 10%, at least 20%, at least 30%, at least 40%, at least 50%, at least 60%, at least 70%, at least 80%, at least 90%, at least 92%, at least 95%, at least 97%, at least 98% or 100% of an RNA molecule, e.g., template RNA and/or a mRNA encoding the gene modifying polypeptide.

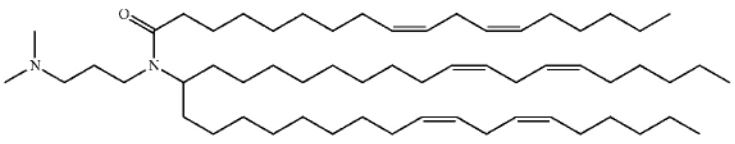
In some embodiments, the lipid to nucleic acid ratio (mass/mass ratio; w/w ratio) can be in the range of from about 1 : 1 to about 25: 1, from about 10: 1 to about 14: 1, from about 3 : 1 to about 15: 1, from about 4: 1 to about 10: 1, from about 5: 1 to about 9: 1, or about 6: 1 to about 9: 1. The amounts of lipids and nucleic acid can be adjusted to provide a desired N/P ratio, for example, N/P ratio of 3, 4, 5, 6, 7, 8, 9, 10 or higher. Generally, the lipid nanoparticle formulation’s overall lipid content can range from about 5 mg/ml to about 30 mg/mL.



Exemplary ionizable lipids that can be used in lipid nanoparticle formulations include, without limitation, those listed in Table 1 of WO2019051289, incorporated herein by reference. Additional exemplary lipids include, without limitation, one or more of the following formulae: X of US2016/0311759; I of US20150376115 or in US2016/0376224; I, II or III of US20160151284; I, IA, II, or IIA of US20170210967; I-c of US20150140070; A of

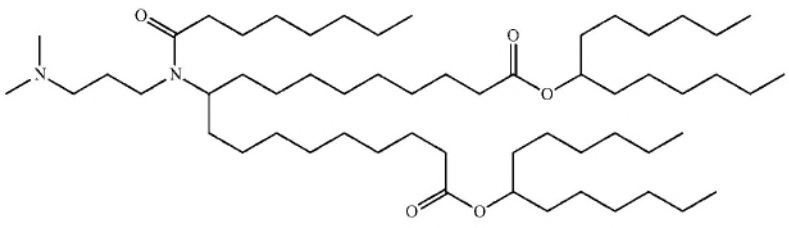
US2013/0178541; I of US2013/0303587 or US2013/0123338; I of US2015/0141678; II, III, IV, or V of US2015/0239926; I of US2017/0119904; I or II of WO2017/117528; A of US2012/0149894; A of US2015/0057373; A of WO2013/116126; A of US2013/0090372; A of US2013/0274523; A of US2013/0274504; A of US2013/0053572; A of W02013/016058; A of W02012/162210; I of US2008/042973; I, II, III, or IV of US2012/01287670; I or II of US2014/0200257; I, II, or III of US2015/0203446; I or III of US2015/0005363; I, IA, IB, IC, ID, II, IIA, IIB, IIC, IID, or III-XXIV of US2014/0308304; of US2013/0338210; I, II, III, or IV of W02009/132131; A of US2012/01011478; I or XXXV of US2012/0027796; XIV or XVII of US2012/0058144; of US2013/0323269; I of US2011/0117125; I, II, or III of US2011/0256175; I, II, III, IV, V, VI, VII, VIII, IX, X, XI, XII of US2012/0202871; I, II, III, IV, V, VI, VII, VIII, X, XII, XIII, XIV, XV, or XVI of US2011/0076335; I or II of US2006/008378; I of US2013/0123338; I or X-A-Y-Z of US2015/0064242; XVI, XVII, or XVIII of US2013/0022649; I, II, or III of US2013/0116307; I, II, or III of US2013/0116307; I or II of US2010/0062967; I-X of US2013/0189351; I of US2014/0039032; V of US2018/0028664; I of US2016/0317458; I of US2013/0195920; 5, 6, or 10 of US10,221,127; III-3 of WO2018/081480; I-5 or I-8 of WO2020/081938; 18 or 25 of US9,867,888; A of US2019/0136231; II of WO2020/219876; 1 of US2012/0027803; OF-02 of US2019/0240349; 23 of US10,086,013; cKK-E12/A6 of Miao et al (2020); C12-200 of WO2010/053572; 7C1 of Dahlman et al (2017); 304-O13 or 503-O13 of Whitehead et al; TS-P4C2 of US9,708,628; I of WO2020/106946; I of WO2020/106946.

In some embodiments, the ionizable lipid is MC3 (6Z,9Z,28Z,3 lZ)-heptatriaconta-6,9,28,3 l-tetraen-l9-yl-4-(dimethylamino) butanoate (DLin-MC3-DMA or MC3), e.g., as described in Example 9 of WO2019051289A9 (incorporated by reference herein in its entirety). In some embodiments, the ionizable lipid is the lipid ATX-002, e.g., as described in Example 10 of WO2019051289A9 (incorporated by reference herein in its entirety). In some embodiments, the ionizable lipid is (l3Z,l6Z)-A,A-dimethyl-3- nonyldocosa-l3, l6-dien-l-amine (Compound 32), e.g., as described in Example 11 of WO2019051289A9 (incorporated by reference herein in its entirety). In some embodiments, the ionizable lipid is Compound 6 or Compound 22, e.g., as described in Example 12 of WO2019051289A9 (incorporated by reference herein in its entirety). In some embodiments, the ionizable lipid is heptadecan-9-yl 8-((2-hydroxyethyl)(6-oxo-6-(undecyloxy)hexyl)amino)octanoate (SM-102); e.g., as described in Example 1 of



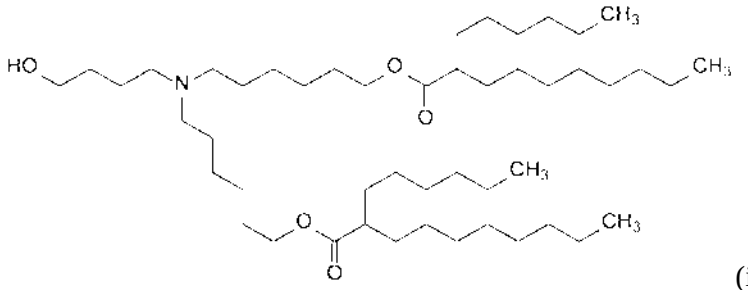
US9,867,888(incorporated by reference herein in its entirety). In some embodiments, the ionizable lipid is 9Z,12Z)-3-((4,4-bis(octyloxy)butanoyl)oxy)-2-((((3-(diethylamino)propoxy)carbonyl)oxy)methyl)propyl octadeca-9,12-dienoate (LP01) e.g., as synthesized in Example 13 of WO2015/095340(incorporated by reference herein in its entirety). In some embodiments, the ionizable lipid is Di((Z)-non-2-en-1-yl) 9-((4-dimethylamino)butanoyl)oxy)heptadecanedioate (L319), e.g. as synthesized in Example 7, 8, or 9 of US2012/0027803(incorporated by reference herein in its entirety). In some embodiments, the ionizable lipid is 1,1'-((2-(4-(2-((2-(Bis(2-hydroxydodecyl)amino)ethyl)(2-hydroxydodecyl) amino)ethyl)piperazin-1-yl)ethyl)azanediyl)bis(dodecan-2-ol) (C12-200), e.g., as synthesized in Examples 14 and 16 of WO2010/053572(incorporated by reference herein in its entirety). In some embodiments, the ionizable lipid is; Imidazole cholesterol ester (ICE) lipid (3S, 10R, 13R, 17R)-10, 13-dimethyl-17- ((R)-6-methylheptan-2-yl)-2, 3, 4, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17-tetradecahydro-lH- cyclopenta[a]phenanthren-3-yl 3-(1H-imidazol-4-yl)propanoate, e.g., Structure (I) from WO2020/106946 (incorporated by reference herein in its entirety).

Some non-limiting examples of lipid compounds that may be used (e.g., in combination with other lipid components) to form lipid nanoparticles for the delivery of compositions described herein, e.g., nucleic acid (e.g., RNA) described herein (e.g., a template nucleic acid or a nucleic acid encoding a gene modifying polypeptide) includes,



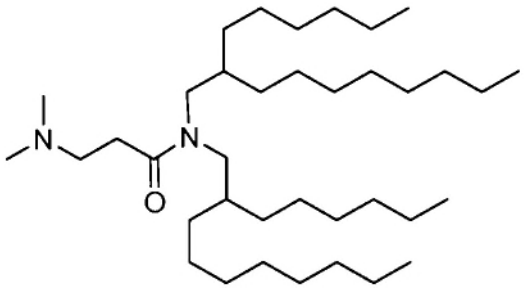
(i)

In some embodiments an LNP comprising Formula (i) is used to deliver a gene modifying composition described herein to the liver and/or hepatocyte cells.



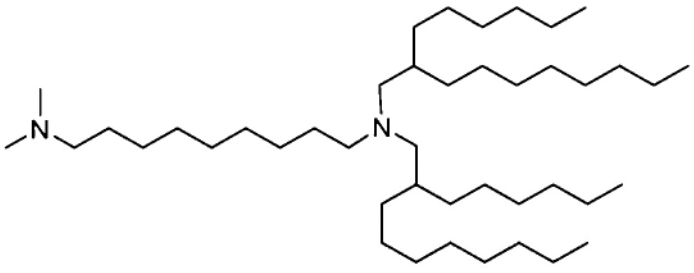
(ii)

In some embodiments an LNP comprising Formula (ii) is used to deliver a gene modifying composition described herein to the liver and/or hepatocyte cells.

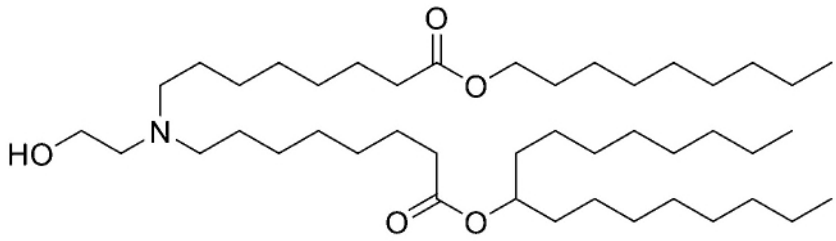


(iii)

In some embodiments an LNP comprising Formula (iii) is used to deliver a gene modifying composition described herein to the liver and/or hepatocyte cells.

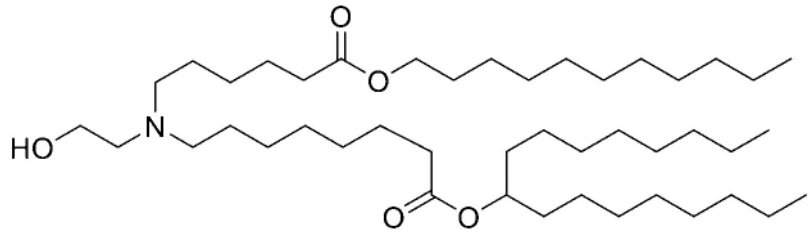


(iv)



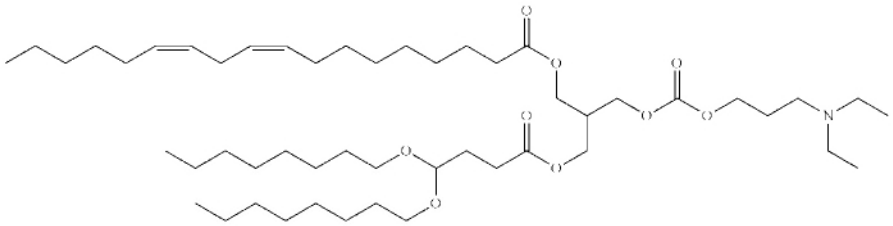
(v)

In some embodiments an LNP comprising Formula (v) is used to deliver a gene modifying composition described herein to the liver and/or hepatocyte cells.

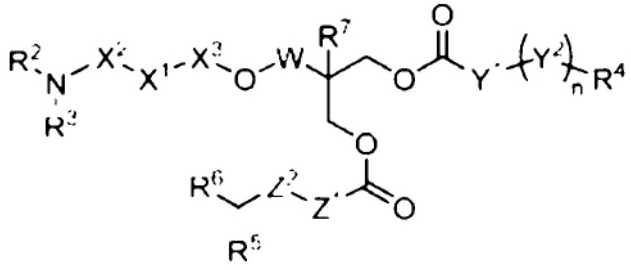


(vi)

In some embodiments an LNP comprising Formula (vi) is used to deliver a gene modifying composition described herein to the liver and/or hepatocyte cells.



(vii)

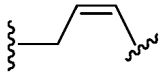


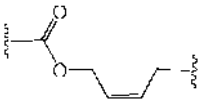
(viii)

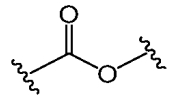
In some embodiments an LNP comprising Formula (viii) is used to deliver a gene modifying composition described herein to the liver and/or hepatocyte cells.

(ix)

In some embodiments an LNP comprising Formula (ix) is used to deliver a gene modifying composition described herein to the liver and/or hepatocyte cells.

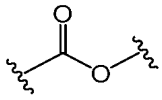






(x)

wherein



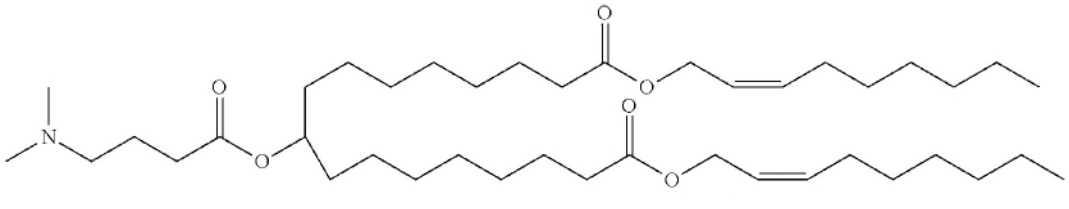
X^1 is O, NR^1, or a direct bond, X^2 is C2-5 alkylene, X^3 is C(=0) or a direct bond, R^1 is H or Me, R^3 is Ci-3 alkyl, R^2 is Ci-3 alkyl, or R^2 taken together with the nitrogen atom to which it is

attached and 1-3 carbon atoms of X^2 form a 4-, 5-, or 6-membered ring, or X^1 is NR^1, R^1 and R^2 taken together with the nitrogen atoms to which they are attached form a 5- or 6-membered ring, or R^2 taken together with R^3 and the nitrogen atom to which they are attached form a 5-, 6-, or 7-membered ring, Y^1 is C2-12 alkylene, Y^2 is selected from

(in either orientation), (in either orientation), (in either orientation),

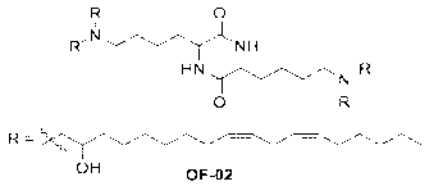
n is 0 to 3, R^4 is Ci-15 alkyl, Z^1 is Ci-6 alkylene or a direct bond,

Z^2 is 



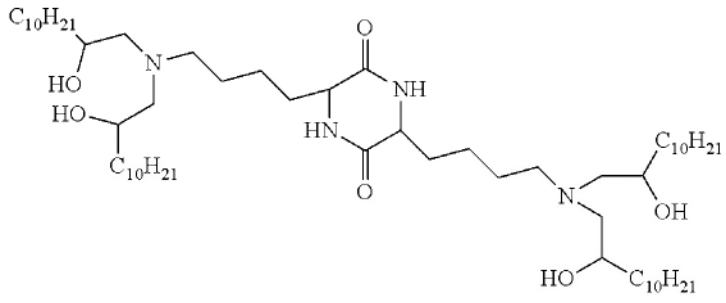
(in either orientation) or absent, provided that if Z^1 is a direct bond, Z^2 is absent;

R^5 is C5-9 alkyl or C6-10 alkoxy, R^6 is C5-9 alkyl or C6-10 alkoxy, W is methylene or a direct bond, and R^7 is H or Me, or a salt thereof, provided that if R^3 and R^2 are C2 alkyls, X^1 is O, X^2 is linear C3 alkylene, X^3 is C(=0), Y^1 is linear Ce alkylene, (Y^2)n-R^4 is



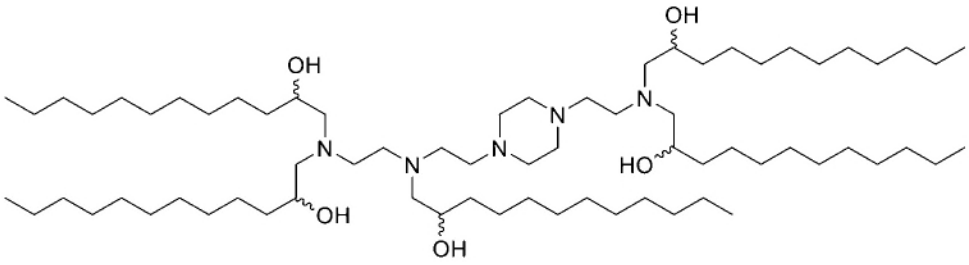
, R^4 is linear C5 alkyl, Z^1 is C2 alkylene, Z^2 is absent, W is methylene, and R^7 is H, then R^5 and R^6 are not Cx alkoxy.

In some embodiments an LNP comprising Formula (xii) is used to deliver a gene modifying composition described herein to the liver and/or hepatocyte cells.



(xi)

In some embodiments an LNP comprising Formula (xi) is used to deliver a gene modifying composition described herein to the liver and/or hepatocyte cells.



where R=  (xii)

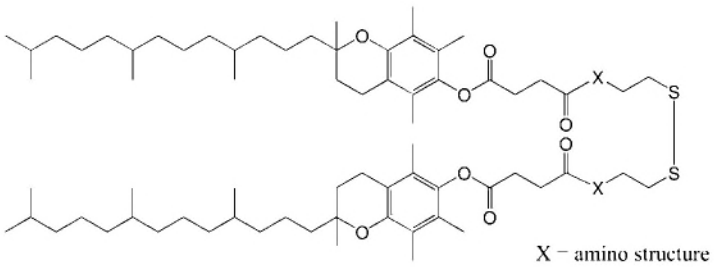
 (xiii)

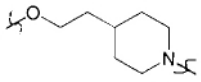
 (xiv)

In some embodiments an LNP comprises a compound of Formula (xiii) and a compound of Formula (xiv).

 (xv)

In some embodiments an LNP comprising Formula (xv) is used to deliver a gene modifying composition described herein to the liver and/or hepatocyte cells.





(xvi)

In some embodiments an LNP comprising a formulation of Formula (xvi) is used to deliver a gene modifying composition described herein to the lung endothelial cells.

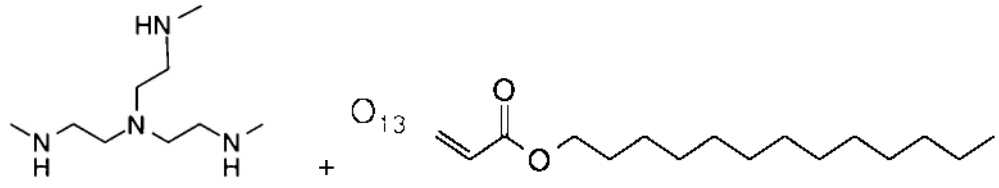
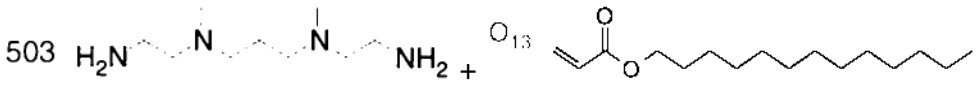
(xviii) (a)

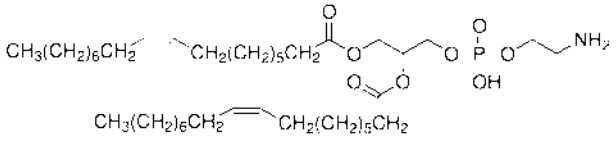


(xviii)(b)



(xix)

In some embodiments, a lipid compound used to form lipid nanoparticles for the delivery of compositions described herein, e.g., nucleic acid (e.g., RNA) described herein (e.g., a template nucleic acid or a nucleic acid encoding a gene modifying polypeptide) is made by one of the following reactions:



(xx) (a)

(xx)(b)

Exemplary non-cationic lipids include, but are not limited to, distearoyl-sn-glycero-phosphoethanolamine, distearoylphosphatidylcholine (DSPC), dioleoylphosphatidylcholine (DOPC), dipalmitoylphosphatidylcholine (DPPC), dioleoylphosphatidylglycerol (DOPG), dipalmitoylphosphatidylglycerol (DPPG), dioleoyl-phosphatidylethanolamine (DOPE), 1,2-dioleoyl-sn-glycero-3-phosphoethanolamine (DOPE), palmitoyloleoylphosphatidylcholine (POPC), palmitoyloleoylphosphatidylethanolamine (POPE), dioleoyl-phosphatidylethanolamine 4-(N-maleimidomethyl)-cyclohexane- 1 - carboxylate (DOPE-mal), dipalmitoyl phosphatidyl ethanolamine (DPPE), dimyristoylphosphoethanolamine (DMPE), distearoyl-phosphatidyl-ethanolamine (DSPE), monomethyl-phosphatidylethanolamine (such as 16-O-monomethyl PE), dimethyl- phosphatidylethanolamine (such as 16-O-dimethyl PE), l8-l-trans PE, l-stearoyl-2-oleoyl- phosphatidyethanolamine (SOPE), hydrogenated soy phosphatidylcholine (HSPC), egg

phosphatidylcholine (EPC), dioleoylphosphatidylserine (DOPS), sphingomyelin (SM), dimyristoyl phosphatidylcholine (DMPC), dimyristoyl phosphatidylglycerol (DMPG), distearoylphosphatidylglycerol (DSPG), dierucoylphosphatidylcholine (DEPC), palmitoyloleyolphosphatidylglycerol (POPG), dielaidoyl-phosphatidylethanolamine (DEPE), lecithin, phosphatidylethanolamine, lysolecithin, lysophosphatidylethanolamine, phosphatidylserine, phosphatidylinositol, sphingomyelin, egg sphingomyelin (ESM), cephalin, cardiolipin, phosphatidicacid,cerebrosides, dicetylphosphate, lysophosphatidylcholine, dilinoleoylphosphatidylcholine, or mixtures thereof. It is understood that other diacylphosphatidylcholine and diacylphosphatidylethanolamine phospholipids can also be used. The acyl groups in these lipids are preferably acyl groups derived from fatty acids having C10-C24 carbon chains, e.g., lauroyl, myristoyl, paimitoyl, stearoyl, or oleoyl. Additional exemplary lipids, in certain embodiments, include, without limitation, those described in Kim et al. (2020) dx.doi.org/10.1021/acs.nanolett.0c01386, incorporated herein by reference. Such lipids include, in some embodiments, plant lipids found to improve liver transfection with mRNA (e.g., DGTS). In some embodiments, the non-cationic lipid may have the following structure,

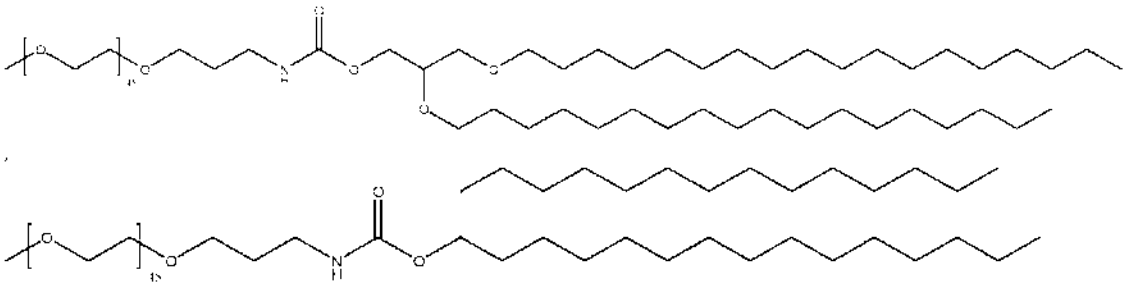
(xxi)

Other examples of non-cationic lipids suitable for use in the lipid nanopartieles include, without limitation, nonphosphorous lipids such as, e.g., stearylamine, dodeeylamine, hexadecylamine, acetyl palmitate, glycerol ricinoleate, hexadecyl stereate, isopropyl myristate, amphoteric acrylic polymers, triethanolamine-lauryl sulfate, alkyl-aryl sulfate polyethyloxylated fatty acid amides, dioctadecyl dimethyl ammonium bromide, ceramide, sphingomyelin, and the like. Other non-cationic lipids are described in WO2017/099823 or US patent publication US2018/0028664, the contents of which is incorporated herein by reference in their entirety.

In some embodiments, the non-cationic lipid is oleic acid or a compound of Formula I, II, or IV of US2018/0028664, incorporated herein by reference in its entirety. The non-cationic lipid can comprise, for example, 0-30% (mol) of the total lipid present in the lipid nanoparticle. In some embodiments, the non-cationic lipid content is 5-20% (mol) or 10-15% (mol) of the total

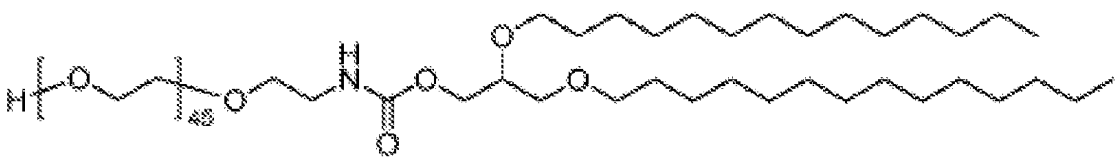
lipid present in the lipid nanoparticle. In embodiments, the molar ratio of ionizable lipid to the neutral lipid ranges from about 2:1 to about 8:1 (e.g., about 2:1, 3:1, 4:1, 5:1, 6:1, 7:1, or 8:1).

In some embodiments, the lipid nanoparticles do not comprise any phospholipids.



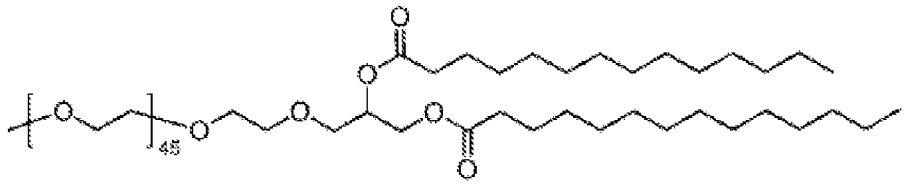
In some aspects, the lipid nanoparticle can further comprise a component, such as a sterol, to provide membrane integrity. One exemplary sterol that can be used in the lipid nanoparticle is cholesterol and derivatives thereof. Non-limiting examples of cholesterol derivatives include polar analogues such as 5a-choiestanol, 53-coprostanol, choiesteryl-(2'-hydroxy)-ethyl ether, choiesteryl-(4'- hydroxy)-butyl ether, and 6-ketocholestanol; non-polar analogues such as 5a-cholestane, cholestenone, 5a-cholestanone, 5p-cholestanone, and cholesteryl decanoate; and mixtures thereof. In some embodiments, the cholesterol derivative is a polar analogue, e.g., choiesteryl-(4'-hydroxy)-buty1 ether. Exemplary cholesterol derivatives are described in PCT publication W02009/127060 and US patent publication US2010/0130588, each of which is incorporated herein by reference in its entirety.

In some embodiments, the component providing membrane integrity, such as a sterol, can comprise 0-50% (mol) (e.g., 0-10%, 10-20%, 20-30%, 30-40%, or 40-50%) of the total lipid present in the lipid nanoparticle. In some embodiments, such a component is 20-50% (mol) 30-40% (mol) of the total lipid content of the lipid nanoparticle.

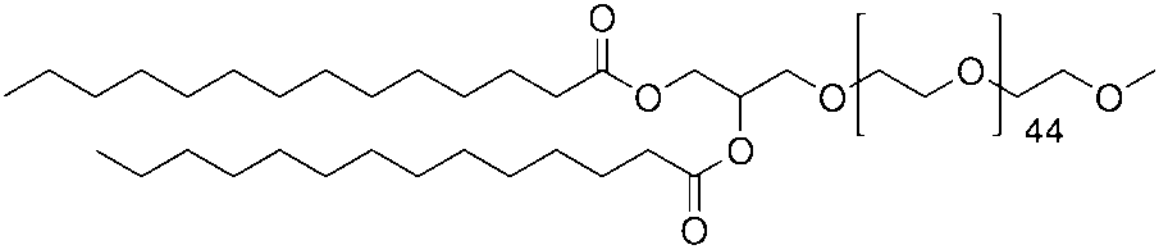


In some embodiments, the lipid nanoparticle can comprise a polyethylene glycol (PEG) or a conjugated lipid molecule. Generally, these are used to inhibit aggregation of lipid nanoparticles and/or provide steric stabilization. Exemplary conjugated lipids include, but are not limited to, PEG-lipid conjugates, polyoxazoline (POZ)-lipid conjugates, polyamide-lipid conjugates (such as ATTA-lipid conjugates), cationic-polymer lipid (CPL) conjugates, and mixtures thereof. In some embodiments, the conjugated lipid molecule is a PEG-lipid conjugate, for example, a (methoxy polyethylene glycol)-conjugated lipid.

Exemplary PEG-lipid conjugates include, but are not limited to, PEG-diacylglycerol (DAG) (such as l-(monomethoxy-polyethyleneglycol)-2,3-dimyristoylglycerol (PEG-DMG)), PEG-dialkyloxypropyl (DAA), PEG-phospholipid, PEG-ceramide (Cer), a pegylated phosphatidylethanoloamine (PEG-PE), 1,2-dimyristoyl-sn-glycerol, methoxypoly ethylene glycol (DMG-PEG-2K), PEG succinate diacylglycerol (PEGS-DAG) (such as 4-0-(2',3'-di(tetradecanoyloxy)propyl-l-0-(w-methoxy(polyethoxy)ethyl) butanedioate (PEG-S-DMG)), PEG dialkoxypropylcarbam, N-(carbonyl-methoxypolyethylene glycol 2000)-l,2-distearoyl-sn-



glycero-3-phosphoethanolamine sodium salt, or a mixture thereof. Additional exemplary PEG-lipid conjugates are described, for example, in US5,885,6l3, US6,287,59l, US2003/0077829, US2003/0077829, US2005/0175682, US2008/0020058, US2011/0117125, US2010/0130588, US2016/0376224, US2017/0119904, and US/099823, the contents of all of which are incorporated herein by reference in their entirety. In some embodiments, a PEG-lipid is a compound of Formula III, III-a-I, III-a-2, III-b-1, III-b-2, or V of US2018/0028664, the content of which is incorporated herein by reference in its entirety. In some embodiments, a PEG-lipid is of Formula II of US20150376115 or US2016/0376224, the content of both of which is incorporated herein by reference in its entirety. In some embodiments, the PEG-DAA conjugate can be, for example, PEG-dilauryloxypropyl, PEG- dimyristyloxypropyl, PEG-dipalmityloxypropyl, or PEG-distearyloxypropyl. The PEG-lipid can be one or more of PEG-DMG, PEG-dilaurylglycerol, PEG-dipalmitoylglycerol, PEG- disterylglycerol, PEG-dilaurylglycamide, PEG-dimyristylglycamide, PEG- dipalmitoylglycamide, PEG-disterylglycamide, PEG-cholesterol (l-[8'-(Cholest-5-en-3[beta]- oxy)carboxamido-3',6'-dioxaoctanyl] carbamoyl-[omega]-methyl-poly(ethylene glycol), PEG- DMB (3,4-Ditetradecoxylbenzyl- [omega]-methyl-poly(ethylene glycol) ether), and 1,2- dimyristoyl-sn-glycero-3-phosphoethanolamine-N-[methoxy(polyethylene glycol)-2000]. In some embodiments, the PEG-lipid comprises PEG-DMG, 1,2- dimyristoyl-sn-glycero-3-phosphoethanolamine-N-[methoxy(polyethylene glycol)-2000]. In some embodiments, the PEG-lipid comprises a structure selected from:



(xxii),

(xxiii),

(xxiv), and

(xxv).

In some embodiments, lipids conjugated with a molecule other than a PEG can also be used in place of PEG-lipid. For example, polyoxazoline (POZ)-lipid conjugates, polyamide-lipid conjugates (such as ATTA-lipid conjugates), and cationic-polymer lipid (GPL) conjugates can be used in place of or in addition to the PEG-lipid.

Exemplary conjugated lipids, i.e., PEG-lipids, (POZ)-lipid conjugates, ATTA-lipid conjugates and cationic polymer-lipids are described in the PCT and LIS patent applications listed in Table 2 of WO2019051289A9 and in WO2020106946A1, the contents of all of which are incorporated herein by reference in their entirety.

In some embodiments an LNP comprises a compound of Formula (xix), a compound of Formula (xxi) and a compound of Formula (xxv). In some embodiments an LNP comprising a formulation of Formula (xix), Formula (xxi) and Formula (xxv)is used to deliver a gene modifying composition described herein to the lung or pulmonary cells.

In some embodiments, a lipid nanoparticle may comprise one or more cationic lipids selected from Formula (i), Formula (ii), Formula (iii), Formula (vii), and Formula (ix). In some embodiments, the LNP may further comprise one or more neutral lipid, e.g., DSPC, DPPC, DMPC, DOPC, POPC, DOPE, SM, a steroid, e.g., cholesterol, and/or one or more polymer conjugated lipid, e.g., a pegylated lipid, e.g., PEG-DAG, PEG-PE, PEG-S-DAG, PEG-cer or a PEG dialkyoxypropylcarbamate.

In some embodiments, the PEG or the conjugated lipid can comprise 0-20% (mol) of the total lipid present in the lipid nanoparticle. In some embodiments, PEG or the conjugated lipid content is 0.5- 10% or 2-5% (mol) of the total lipid present in the lipid nanoparticle. Molar ratios of the ionizable lipid, non-cationic-lipid, sterol, and PEG/conjugated lipid can be varied as needed. For example, the lipid particle can comprise 30-70% ionizable lipid by mole or by total weight of the composition, 0-60% cholesterol by mole or by total weight of the composition, 0-30% non-cationic-lipid by mole or by total weight of the composition and 1-10% conjugated lipid by mole or by total weight of the composition. Preferably, the composition comprises 30-40% ionizable lipid by mole or by total weight of the composition, 40-50% cholesterol by mole or by total weight of the composition, and 10- 20% non-cationic-lipid by mole or by total weight of the composition. In some other embodiments, the composition is 50-75% ionizable lipid by mole or by total weight of the composition, 20-40% cholesterol by mole or by total weight of the composition, and 5 to 10% non-cationic-lipid, by mole or by total weight of the composition and 1-10% conjugated lipid by mole or by total weight of the composition. The composition may contain 60-70% ionizable lipid by mole or by total weight of the composition, 25-35% cholesterol by mole or by total weight of the composition, and 5-10% non-cationic-lipid by mole or by total weight of the composition. The composition may also contain up to 90% ionizable lipid by mole or by total weight of the composition and 2 to 15% non-cationic lipid by mole or by total weight of the composition. The formulation may also be a lipid nanoparticle formulation, for example comprising 8-30% ionizable lipid by mole or by total weight of the composition, 5-30% non- cationic lipid by mole or by total weight of the composition, and 0-20% cholesterol by mole or by total weight of the composition; 4-25% ionizable lipid by mole or by total weight of the composition, 4-25% non-cationic lipid by mole or by total weight of the composition, 2 to 25% cholesterol by mole or by total weight of the composition, 10 to 35% conjugate lipid by mole or by total weight of the composition, and 5% cholesterol by mole or by total weight of the composition; or 2-30% ionizable lipid by mole or by total weight of the composition, 2-30% non-cationic lipid by mole or by total weight of the composition, 1 to 15% cholesterol by mole or by total weight of the composition, 2 to 35% conjugate lipid by mole or by total weight of the composition, and 1-20% cholesterol by mole or by total weight of the composition; or even up to 90% ionizable lipid by mole or by total weight of the composition and 2-10% non-cationic lipids by mole or by total weight of the composition, or even 100% cationic lipid by mole or by total

weight of the composition. In some embodiments, the lipid particle formulation comprises ionizable lipid, phospholipid, cholesterol and a PEG-ylated lipid in a molar ratio of 50: 10:38.5: 1.5. In some other embodiments, the lipid particle formulation comprises ionizable lipid, cholesterol and a PEG-ylated lipid in a molar ratio of 60:38.5: 1.5.

In some embodiments, the lipid particle comprises ionizable lipid, non-cationic lipid (e.g. phospholipid), a sterol (e.g., cholesterol) and a PEG-ylated lipid, where the molar ratio of lipids ranges from 20 to 70 mole percent for the ionizable lipid, with a target of 40-60, the mole percent of non-cationic lipid ranges from 0 to 30, with a target of 0 to 15, the mole percent of sterol ranges from 20 to 70, with a target of 30 to 50, and the mole percent of PEG-ylated lipid ranges from 1 to 6, with a target of 2 to 5.

In some embodiments, the lipid particle comprises ionizable lipid / non-cationic- lipid / sterol / conjugated lipid at a molar ratio of 50: 10:38.5: 1.5.

In an aspect, the disclosure provides a lipid nanoparticle formulation comprising phospholipids, lecithin, phosphatidylcholine and phosphatidylethanolamine.

In some embodiments, one or more additional compounds can also be included. Those compounds can be administered separately or the additional compounds can be included in the lipid nanoparticles of the invention. In other words, the lipid nanoparticles can contain other compounds in addition to the nucleic acid or at least a second nucleic acid, different than the first. Without limitations, other additional compounds can be selected from the group consisting of small or large organic or inorganic molecules, monosaccharides, disaccharides, trisaccharides, oligosaccharides, polysaccharides, peptides, proteins, peptide analogs and derivatives thereof, peptidomimetics, nucleic acids, nucleic acid analogs and derivatives, an extract made from biological materials, or any combinations thereof.

In some embodiments, a lipid nanoparticle (or a formulation comprising lipid nanoparticles) lacks reactive impurities (e.g., aldehydes or ketones), or comprises less than a preselected level of reactive impurities (e.g., aldehydes or ketones). While not wishing to be bound by theory, in some embodiments, a lipid reagent is used to make a lipid nanoparticle formulation, and the lipid reagent may comprise a contaminating reactive impurity (e.g., an aldehyde or ketone). A lipid regent may be selected for manufacturing based on having less than a preselected level of reactive impurities (e.g., aldehydes or ketones). Without wishing to be bound by theory, in some embodiments, aldehydes can cause modification and damage of RNA,

e.g., cross-linking between bases and/or covalently conjugating lipid to RNA (e.g., forming lipid-RNA adducts). This may, in some instances, lead to failure of a reverse transcriptase reaction and/or incorporation of inappropriate bases, e.g., at the site(s) of lesion(s), e.g., a mutation in a newly synthesized target DNA.

In some embodiments, a lipid nanoparticle formulation is produced using a lipid reagent comprising less than 5%, 4%, 3%, 2%, 1%, 0.9%, 0.8%, 0.7%, 0.6%, 0.5%, 0.4%, 0.3%, 0.2%, or 0.1% total reactive impurity (e.g., aldehyde) content. In some embodiments, a lipid nanoparticle formulation is produced using a lipid reagent comprising less than 5%, 4%, 3%, 2%, 1%, 0.9%, 0.8%, 0.7%, 0.6%, 0.5%, 0.4%, 0.3%, 0.2%, or 0.1% of any single reactive impurity (e.g., aldehyde) species. In some embodiments, a lipid nanoparticle formulation is produced using a lipid reagent comprising: (i) less than 5%, 4%, 3%, 2%, 1%, 0.9%, 0.8%, 0.7%, 0.6%, 0.5%, 0.4%, 0.3%, 0.2%, or 0.1% total reactive impurity (e.g., aldehyde) content; and (ii) less than 5%, 4%, 3%, 2%, 1%, 0.9%, 0.8%, 0.7%, 0.6%, 0.5%, 0.4%, 0.3%, 0.2%, or 0.1% of any single reactive impurity (e.g., aldehyde) species. In some embodiments, the lipid nanoparticle formulation is produced using a plurality of lipid reagents, and each lipid reagent of the plurality independently meets one or more criterion described in this paragraph. In some embodiments, each lipid reagent of the plurality meets the same criterion, e.g., a criterion of this paragraph.

In some embodiments, the lipid nanoparticle formulation comprises less than 5%, 4%, 3%, 2%, 1%, 0.9%, 0.8%, 0.7%, 0.6%, 0.5%, 0.4%, 0.3%, 0.2%, or 0.1% total reactive impurity (e.g., aldehyde) content. In some embodiments, the lipid nanoparticle formulation comprises less than 5%, 4%, 3%, 2%, 1%, 0.9%, 0.8%, 0.7%, 0.6%, 0.5%, 0.4%, 0.3%, 0.2%, or 0.1% of any single reactive impurity (e.g., aldehyde) species. In some embodiments, the lipid nanoparticle formulation comprises: (i) less than 5%, 4%, 3%, 2%, 1%, 0.9%, 0.8%, 0.7%, 0.6%, 0.5%, 0.4%, 0.3%, 0.2%, or 0.1% total reactive impurity (e.g., aldehyde) content; and (ii) less than 5%, 4%, 3%, 2%, 1%, 0.9%, 0.8%, 0.7%, 0.6%, 0.5%, 0.4%, 0.3%, 0.2%, or 0.1% of any single reactive impurity (e.g., aldehyde) species.

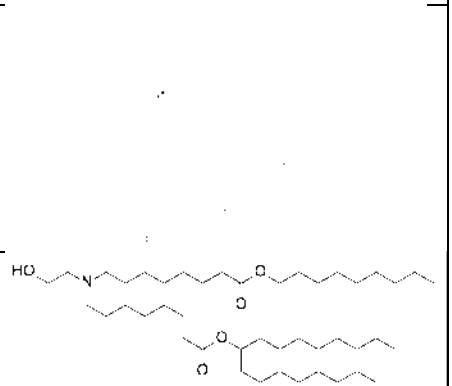
In some embodiments, one or more, or optionally all, of the lipid reagents used for a lipid nanoparticle as described herein or a formulation thereof comprise less than 5%, 4%, 3%, 2%, 1%, 0.9%, 0.8%, 0.7%, 0.6%, 0.5%, 0.4%, 0.3%, 0.2%, or 0.1% total reactive impurity (e.g., aldehyde) content. In some embodiments, one or more, or optionally all, of the lipid reagents used for a lipid nanoparticle as described herein or a formulation thereof comprise less than 5%,

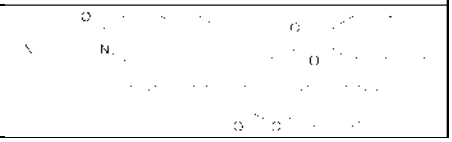
4%, 3%, 2%, 1%, 0.9%, 0.8%, 0.7%, 0.6%, 0.5%, 0.4%, 0.3%, 0.2%, or 0.1% of any single reactive impurity (e.g., aldehyde) species. In some embodiments, one or more, or optionally all, of the lipid reagents used for a lipid nanoparticle as described herein or a formulation thereof comprise: (i) less than 5%, 4%, 3%, 2%, 1%, 0.9%, 0.8%, 0.7%, 0.6%, 0.5%, 0.4%, 0.3%, 0.2%, or 0.1% total reactive impurity (e.g., aldehyde) content; and (ii) less than 5%, 4%, 3%, 2%, 1%, 0.9%, 0.8%, 0.7%, 0.6%, 0.5%, 0.4%, 0.3%, 0.2%, or 0.1% of any single reactive impurity (e.g., aldehyde) species.

In some embodiments, total aldehyde content and/or quantity of any single reactive impurity (e.g., aldehyde) species is determined by liquid chromatography (LC), e.g., coupled with tandem mass spectrometry (MS/MS), e.g., according to the method described in Example 40 of PCT/US21/20948. In some embodiments, reactive impurity (e.g., aldehyde) content and/or quantity of reactive impurity (e.g., aldehyde) species is determined by detecting one or more chemical modifications of a nucleic acid molecule (e.g., an RNA molecule, e.g., as described herein) associated with the presence of reactive impurities (e.g., aldehydes), e.g., in the lipid reagents. In some embodiments, reactive impurity (e.g., aldehyde) content and/or quantity of reactive impurity (e.g., aldehyde) species is determined by detecting one or more chemical modifications of a nucleotide or nucleoside (e.g., a ribonucleotide or ribonucleoside, e.g., comprised in or isolated from a template nucleic acid, e.g., as described herein) associated with the presence of reactive impurities (e.g., aldehydes), e.g., in the lipid reagents, e.g., according to the method described in Example 41 of PCT/US21/20948. In embodiments, chemical modifications of a nucleic acid molecule, nucleotide, or nucleoside are detected by determining the presence of one or more modified nucleotides or nucleosides, e.g., using LC-MS/MS analysis, e.g., according to the method described in Example 41 of PCT/US21/20948.

In some embodiments, a nucleic acid (e.g., RNA) described herein (e.g., a template nucleic acid or a nucleic acid encoding a gene modifying polypeptide) does not comprise an aldehyde modification, or comprises less than a preselected amount of aldehyde modifications. In some embodiments, on average, a nucleic acid has less than 50, 20, 10, 5, 2, or 1 aldehyde modifications per 1000 nucleotides, e.g., wherein a single cross-linking of two nucleotides is a single aldehyde modification. In some embodiments, the aldehyde modification is an RNA adduct (e.g., a lipid-RNA adduct). In some embodiments, the aldehyde-modified nucleotide is

cross-linking between bases . In some embodiments, a nucleic acid (e.g., RNA) described herein comprises less than 50, 20, 10, 5, 2, or 1 cross-links between nucleotide.





In some embodiments, LNPs are directed to specific tissues by the addition of targeting domains. For example, biological ligands may be displayed on the surface of LNPs to enhance interaction with cells displaying cognate receptors, thus driving association with and cargo delivery to tissues wherein cells express the receptor. In some embodiments, the biological ligand may be a ligand that drives delivery to the liver, e.g., LNPs that display GalNAc result in delivery of nucleic acid cargo to hepatocytes that display asialoglycoprotein receptor (ASGPR). The work of Akinc et al. *Mol Ther* 18(7):1357-1364 (2010) teaches the conjugation of a trivalent GalNAc ligand to a PEG-lipid (GalNAc-PEG-DSG) to yield LNPs dependent on ASGPR for observable LNP cargo effect (see, e.g., Figure 6 therein). Other ligand-displaying LNP formulations, e.g., incorporating folate, transferrin, or antibodies, are discussed in WO2017223135, which is incorporated herein by reference in its entirety, in addition to the references used therein, namely Kolhatkar et al., Curr Drug Discov Technol. 2011 8:197-206; Musacchio and Torchilin, Front Biosci. 2011 16:1388-1412; Yu et al., Mol Membr Biol. 2010 27:286-298; Patil et al., Crit Rev Ther Drug Carrier Syst. 2008 25:1-61 ; Benoit et al., Biomacromolecules. 2011 12:2708-2714; Zhao et al., Expert Opin Drug Deliv. 2008 5:309-319; Akinc et al., Mol Ther. 2010 18:1357-1364; Srinivasan et al., Methods Mol Biol. 2012 820:105-116; Ben-Arie et al., Methods Mol Biol. 2012 757:497-507; Peer 2010 J Control Release. 20:63-68; Peer et al., Proc Natl Acad Sci U S A. 2007 104:4095-4100; Kim et al., Methods Mol Biol. 2011 721:339-353; Subramanya et al., Mol Ther. 2010 18:2028-2037; Song et al., Nat Biotechnol. 2005 23:709-717; Peer et al., Science. 2008 319:627-630; and Peer and Lieberman, Gene Ther. 2011 18:1127-1133.

In some embodiments, LNPs are selected for tissue-specific activity by the addition of a Selective ORgan Targeting (SORT) molecule to a formulation comprising traditional components, such as ionizable cationic lipids, amphipathic phospholipids, cholesterol and poly(ethylene glycol) (PEG) lipids. The teachings of Cheng et al. Nat Nanotechnol 15(4):313-320 (2020) demonstrate that the addition of a supplemental “SORT” component precisely alters the *in vivo* RNA delivery profile and mediates tissue-specific (e.g., lungs, liver, spleen) gene delivery and editing as a function of the percentage and biophysical property of the SORT molecule.

In some embodiments, the LNPs comprise biodegradable, ionizable lipids. In some embodiments, the LNPs comprise (9Z,l2Z)-3-((4,4-bis(octyloxy)butanoyl)oxy)-2-((((3-(diethylamino)propoxy)carbonyl)oxy)methyl)propyl octadeca-9,l2-dienoate, also called 3- ((4,4-bis(octyloxy)butanoyl)oxy)-2-((((3-(diethylamino)propoxy)carbonyl)oxy)methyl)propyl (9Z,l2Z)-octadeca-9,l2-dienoate) or another ionizable lipid. See, e.g, lipids of WO2019/067992, WO/2017/173054, WO2015/095340, and WO2014/136086, as well as references provided therein. In some embodiments, the term cationic and ionizable in the context of LNP lipids is interchangeable, e.g., wherein ionizable lipids are cationic depending on the pH.

In some embodiments, an LNP described herein comprises a lipid described in Table 19.

Table 19: Exemplary Lipids

LIPID ID	Chemical Name	Molecular Weight	Structure
LIPIDV003	(9Z,12Z)-3-((4,4-bis(octyloxy)butanoyl)oxy)-2-((((3-(diethylamino)propoxy)carbonyl)oxy)methyl)propyl octadeca-9,12-dienoate	852.29	
LIPIDV004	Heptadecan-9-yl 8-((2-hydroxyethyl)(8-(nonyloxy)-8-oxooctyl)amino)octanoate	710.18	
LIPIDV005		919.56	

In some embodiments, multiple components of a gene modifying system may be prepared as a single LNP formulation, e.g., an LNP formulation comprises mRNA encoding for the gene modifying polypeptide and an RNA template. Ratios of nucleic acid components may be varied in order to maximize the properties of a therapeutic. In some embodiments, the ratio of RNA template to mRNA encoding a gene modifying polypeptide is about 1:1 to 100:1, e.g., about 1:1 to 20:1, about 20:1 to 40:1, about 40:1 to 60:1, about 60:1 to 80:1, or about 80:1 to 100:1, by molar ratio. In other embodiments, a system of multiple nucleic acids may be prepared by separate formulations, e.g., one LNP formulation comprising a template RNA and a second

LNP formulation comprising an mRNA encoding a gene modifying polypeptide. In some embodiments, the system may comprise more than two nucleic acid components formulated into LNPs. In some embodiments, the system may comprise a protein, e.g., a gene modifying polypeptide, and a template RNA formulated into at least one LNP formulation.

In some embodiments, the average LNP diameter of the LNP formulation may be between 10s of nm and 100s of nm, e.g., measured by dynamic light scattering (DLS). In some embodiments, the average LNP diameter of the LNP formulation may be from about 40 nm to about 150 nm, such as about 40 nm, 45 nm, 50 nm, 55 nm, 60 nm, 65 nm, 70 nm, 75 nm, 80 nm, 85 nm, 90 nm, 95 nm, 100 nm, 105 nm, 110 nm, 115 nm, 120 nm, 125 nm, 130 nm, 135 nm, 140 nm, 145 nm, or 150 nm. In some embodiments, the average LNP diameter of the LNP formulation may be from about 50 nm to about 100 nm, from about 50 nm to about 90 nm, from about 50 nm to about 80 nm, from about 50 nm to about 70 nm, from about 50 nm to about 60 nm, from about 60 nm to about 100 nm, from about 60 nm to about 90 nm, from about 60 nm to about 80 nm, from about 60 nm to about 70 nm, from about 70 nm to about 100 nm, from about 70 nm to about 90 nm, from about 70 nm to about 80 nm, from about 80 nm to about 100 nm, from about 80 nm to about 90 nm, or from about 90 nm to about 100 nm. In some embodiments, the average LNP diameter of the LNP formulation may be from about 70 nm to about 100 nm. In a particular embodiment, the average LNP diameter of the LNP formulation may be about 80 nm. In some embodiments, the average LNP diameter of the LNP formulation may be about 100 nm. In some embodiments, the average LNP diameter of the LNP formulation ranges from about l mm to about 500 mm, from about 5 mm to about 200 mm, from about 10 mm to about 100 mm, from about 20 mm to about 80 mm, from about 25 mm to about 60 mm, from about 30 mm to about 55 mm, from about 35 mm to about 50 mm, or from about 38 mm to about 42 mm.

An LNP may, in some instances, be relatively homogenous. A polydispersity index may be used to indicate the homogeneity of an LNP, e.g., the particle size distribution of the lipid nanoparticles. A small (e.g., less than 0.3) polydispersity index generally indicates a narrow particle size distribution. An LNP may have a polydispersity index from about 0 to about 0.25, such as 0.01, 0.02, 0.03, 0.04, 0.05, 0.06, 0.07, 0.08, 0.09, 0.10, 0.11, 0.12, 0.13, 0.14, 0.15, 0.16, 0.17, 0.18, 0.19, 0.20, 0.21, 0.22, 0.23, 0.24, or 0.25. In some embodiments, the polydispersity index of an LNP may be from about 0.10 to about 0.20.

The zeta potential of an LNP may be used to indicate the electrokinetic potential of the composition. In some embodiments, the zeta potential may describe the surface charge of an LNP. Lipid nanoparticles with relatively low charges, positive or negative, are generally desirable, as more highly charged species may interact undesirably with cells, tissues, and other elements in the body. In some embodiments, the zeta potential of an LNP may be from about -10 mV to about +20 mV, from about -10 mV to about +15 mV, from about -10 mV to about +10 mV, from about -10 mV to about +5 mV, from about -10 mV to about 0 mV, from about -10 mV to about -5 mV, from about -5 mV to about +20 mV, from about -5 mV to about +15 mV, from about -5 mV to about +10 mV, from about -5 mV to about +5 mV, from about -5 mV to about 0 mV, from about 0 mV to about +20 mV, from about 0 mV to about +15 mV, from about 0 mV to about +10 mV, from about 0 mV to about +5 mV, from about +5 mV to about +20 mV, from about +5 mV to about +15 mV, or from about +5 mV to about +10 mV.

The efficiency of encapsulation of a protein and/or nucleic acid, e.g., gene modifying polypeptide or mRNA encoding the polypeptide, describes the amount of protein and/or nucleic acid that is encapsulated or otherwise associated with an LNP after preparation, relative to the initial amount provided. The encapsulation efficiency is desirably high (e.g., close to 100%). The encapsulation efficiency may be measured, for example, by comparing the amount of protein or nucleic acid in a solution containing the lipid nanoparticle before and after breaking up the lipid nanoparticle with one or more organic solvents or detergents. An anion exchange resin may be used to measure the amount of free protein or nucleic acid (e.g., RNA) in a solution. Fluorescence may be used to measure the amount of free protein and/or nucleic acid (e.g., RNA) in a solution. For the lipid nanoparticles described herein, the encapsulation efficiency of a protein and/or nucleic acid may be at least 50%, for example 50%, 55%, 60%, 65%, 70%, 75%, 80%, 85%, 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, 99%, or 100%. In some embodiments, the encapsulation efficiency may be at least 80%. In some embodiments, the encapsulation efficiency may be at least 90%. In some embodiments, the encapsulation efficiency may be at least 95%.

An LNP may optionally comprise one or more coatings. In some embodiments, an LNP may be formulated in a capsule, film, or table having a coating. A capsule, film, or tablet including a composition described herein may have any useful size, tensile strength, hardness or density.

Additional exemplary lipids, formulations, methods, and characterization of LNPs are taught by WO2020061457, which is incorporated herein by reference in its entirety.

In some embodiments, *in vitro* or *ex vivo* cell lipofections are performed using Lipofectamine MessengerMax (Thermo Fisher) or TransIT-mRNA Transfection Reagent (Mirus Bio). In certain embodiments, LNPs are formulated using the GenVoy_ILM ionizable lipid mix (Precision NanoSystems). In certain embodiments, LNPs are formulated using 2,2-dilinoleyl-4-dimethylaminoethyl-[1,3]-dioxolane (DLin-KC2-DMA) or dilinoleylmethyl-4-dimethylaminobutyrate (DLin-MC3-DMA or MC3), the formulation and *in vivo* use of which are taught in Jayaraman et al. Angew Chem Int Ed Engl 51(34):8529-8533 (2012), incorporated herein by reference in its entirety.

LNP formulations optimized for the delivery of CRISPR-Cas systems, e.g., Cas9-gRNA RNP, gRNA, Cas9 mRNA, are described in WO2019067992 and WO2019067910, both incorporated by reference.

Additional specific LNP formulations useful for delivery of nucleic acids are described in US8158601 and US8168775, both incorporated by reference, which include formulations used in patisiran, sold under the name ONPATTRO.

Exemplary dosing of gene modifying LNP may include about 0.1, 0.25, 0.3, 0.5, 1, 2, 3, 4, 5, 6, 8, 10, or 100 mg/kg (RNA). Exemplary dosing of AAV comprising a nucleic acid encoding one or more components of the system may include an MOI of about 10^{11}, 10^{12}, 10^{13}, and 10^{14} vg/kg.

Kits, Articles of Manufacture, and Pharmaceutical Compositions

In an aspect the disclosure provides a kit comprising a gene modifying polypeptide or a gene modifying system, e.g., as described herein. In some embodiments, the kit comprises a gene modifying polypeptide (or a nucleic acid encoding the polypeptide) and a template RNA (or DNA encoding the template RNA). In some embodiments, the kit further comprises a reagent for introducing the system into a cell, e.g., transfection reagent, LNP, and the like. In some embodiments, the kit is suitable for any of the methods described herein. In some embodiments, the kit comprises one or more elements, compositions (e.g., pharmaceutical compositions), gene modifying polypeptides, and/or gene modifying systems, or a functional fragment or component

thereof, e.g., disposed in an article of manufacture. In some embodiments, the kit comprises instructions for use thereof.

In an aspect, the disclosure provides an article of manufacture, e.g., in which a kit as described herein, or a component thereof, is disposed.

In an aspect, the disclosure provides a pharmaceutical composition comprising a gene modifying polypeptide or a gene modifying system, e.g., as described herein. In some embodiments, the pharmaceutical composition further comprises a pharmaceutically acceptable carrier or excipient. In some embodiments, the pharmaceutical composition comprises a template RNA and/or an RNA encoding the polypeptide. In embodiments, the pharmaceutical composition has one or more (e.g., 1, 2, 3, or 4) of the following characteristics:

(a) less than 1% (e.g., less than 0.5%, 0.4%, 0.3%, 0.2%, or 0.1%) DNA template relative to the template RNA and/or the RNA encoding the polypeptide, e.g., on a molar basis;

(b) less than 1% (e.g., less than 0.5%, 0.4%, 0.3%, 0.2%, or 0.1%) uncapped RNA relative to the template RNA and/or the RNA encoding the polypeptide, e.g., on a molar basis;

(c) less than 1% (e.g., less than 0.5%, 0.4%, 0.3%, 0.2%, or 0.1%) partial length RNAs relative to the template RNA and/or the RNA encoding the polypeptide, e.g., on a molar basis;

(d) substantially lacks unreacted cap dinucleotides.

Chemistry, Manufacturing, and Controls (CMC)

Purification of protein therapeutics is described, for example, in Franks, Protein Biotechnology: *Isolation, Characterization, and Stabilization*, Humana Press (2013); and in Cutler, *Protein Purification Protocols (Methods in Molecular Biology)*, Humana Press (2010).

In some embodiments, a gene modifying system, polypeptide, and/or template nucleic acid (e.g., template RNA) conforms to certain quality standards. In some embodiments, a gene modifying system, polypeptide, and/or template nucleic acid (e.g., template RNA) produced by a method described herein conforms to certain quality standards. Accordingly, the disclosure is directed, in some aspects, to methods of manufacturing a gene modifying system, polypeptide, and/or template nucleic acid (e.g., template RNA) that conforms to certain quality standards, e.g., in which said quality standards are assayed. The disclosure is also directed, in some aspects, to methods of assaying said quality standards in a gene modifying system, polypeptide, and/or

template nucleic acid (e.g., template RNA). In some embodiments, quality standards include, but are not limited to, one or more (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, or 12) of the following:

(i) the length of the template RNA, e.g., whether the template RNA has a length that is above a reference length or within a reference length range, e.g., whether at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, or 99% of the template RNA present is greater than 100, 125, 150, 175, or 200 nucleotides long;

(ii) the presence, absence, and/or length of a polyA tail on the template RNA, e.g., whether at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, or 99% of the template RNA present contains a polyA tail (e.g., a polyA tail that is at least 5, 10, 20, 30, 50, 70, 100 nucleotides in length (SEQ ID NO: 37640));

(iii) the presence, absence, and/or type of a 5´ cap on the template RNA, e.g., whether at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, or 99% of the template RNA present contains a 5´ cap, e.g., whether that cap is a 7-methylguanosine cap, e.g., a O-Me-m7G cap;

(iv) the presence, absence, and/or type of one or more modified nucleotides (e.g., selected from pseudouridine, dihydrouridine, inosine, 7-methylguanosine, 1-N-methylpseudouridine (1-Me-Ψ), 5-methoxyuridine (5-MO-U), 5-methylcytidine (5mC), or a locked nucleotide) in the template RNA, e.g., whether at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, or 99% of the template RNA present contains one or more modified nucleotides;

(v) the stability of the template RNA (e.g., over time and/or under a pre-selected condition), e.g., whether at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, or 99% of the template RNA remains intact (e.g., greater than 100, 125, 150, 175, or 200 nucleotides long) after a stability test;

(vi) the potency of the template RNA in a system for modifying DNA, e.g., whether at least 1% of target sites are modified after a system comprising the template RNA is assayed for potency;

(vii) the length of the polypeptide, first polypeptide, or second polypeptide, e.g., whether the polypeptide, first polypeptide, or second polypeptide has a length that is above a reference length or within a reference length range, e.g., whether at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, or 99% of the polypeptide, first polypeptide, or second polypeptide present is greater than 600, 650, 700, 750, 800, 850, 900, 950, 1000, 1050, 1100, 1150, 1200, 1250, 1300, 1350, 1400,

1450, 1500, 1600, 1700, 1800, 1900, or 2000 amino acids long (and optionally, no larger than 2500, 2000, 1500, 1400, 1300, 1200, 1100, 1000, 900, 800, 700, or 600 amino acids long);

(viii) the presence, absence, and/or type of post-translational modification on the polypeptide, first polypeptide, or second polypeptide, e.g., whether at least 80, 85, 90, 95, 96, 97, 98, or 99% of the polypeptide, first polypeptide, or second polypeptide contains phosphorylation, methylation, acetylation, myristoylation, palmitoylation, isoprenylation, glipyatyon, or lipoylation, or any combination thereof;

(ix) the presence, absence, and/or type of one or more artificial, synthetic, or non-canonical amino acids (e.g., selected from ornithine, β-alanine, GABA, δ-Aminolevulinic acid, PABA, a D-amino acid (e.g., D-alanine or D-glutamate), aminoisobutyric acid, dehydroalanine, cystathionine, lanthionine, Djenkolic acid, Diaminopimelic acid, Homoalanine, Norvaline, Norleucine, Homonorleucine, homoserine, O-methyl-homoserine and O-ethyl-homoserine, ethionine, selenocysteine, selenohomocysteine, selenomethionine, selenoethionine, tellurocysteine, or telluromethionine) in the polypeptide, first polypeptide, or second polypeptide, e.g., whether at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, or 99% of the polypeptide, first polypeptide, or second polypeptide present contains one or more artificial, synthetic, or non-canonical amino acids;

(x) the stability of the polypeptide, first polypeptide, or second polypeptide (e.g., over time and/or under a pre-selected condition), e.g., whether at least 80%, 85%, 90%, 95%, 96%, 97%, 98%, or 99% of the polypeptide, first polypeptide, or second polypeptide remains intact (e.g., greater than 600, 650, 700, 750, 800, 850, 900, 950, 1000, 1050, 1100, 1150, 1200, 1250, 1300, 1350, 1400, 1450, 1500, 1600, 1700, 1800, 1900, or 2000 amino acids long (and optionally, no larger than 2500, 2000, 1500, 1400, 1300, 1200, 1100, 1000, 900, 800, 700, or 600 amino acids long)) after a stability test;

(xi) the potency of the polypeptide, first polypeptide, or second polypeptide in a system for modifying DNA, e.g., whether at least 1% of target sites are modified after a system comprising the polypeptide, first polypeptide, or second polypeptide is assayed for potency; or

(xii) the presence, absence, and/or level of one or more of a pyrogen, virus, fungus, bacterial pathogen, or host cell protein, e.g., whether the system is free or substantially free of pyrogen, virus, fungus, bacterial pathogen, or host cell protein contamination.

In some embodiments, a system or pharmaceutical composition described herein is endotoxin free.

In some embodiments, the presence, absence, and/or level of one or more of a pyrogen, virus, fungus, bacterial pathogen, and/or host cell protein is determined. In embodiments, whether the system is free or substantially free of pyrogen, virus, fungus, bacterial pathogen, and/or host cell protein contamination is determined.

In some embodiments, a pharmaceutical composition or system as described herein has one or more (e.g., 1, 2, 3, or 4) of the following characteristics:

(a) less than 1% (e.g., less than 0.5%, 0.4%, 0.3%, 0.2%, or 0.1%) DNA template relative to the template RNA and/or the RNA encoding the polypeptide, e.g., on a molar basis;

(b) less than 1% (e.g., less than 0.5%, 0.4%, 0.3%, 0.2%, or 0.1%) uncapped RNA relative to the template RNA and/or the RNA encoding the polypeptide, e.g., on a molar basis;

(c) less than 1% (e.g., less than 0.5%, 0.4%, 0.3%, 0.2%, or 0.1%) partial length RNAs relative to the template RNA and/or the RNA encoding the polypeptide, e.g., on a molar basis;

(d) substantially lacks unreacted cap dinucleotides.

EXAMPLES

Example 1: Screening configurations of template RNAs that correct the R408W mutation in a genomic landing pad in human cells

This example describes the use of gene modifying system containing a gene modifying polypeptide and template RNAs comprising varied lengths of heterologous object sequences and PBS sequences to quantify the activity of template RNAs for correction of the R408W mutation. In this example, a template RNA contains:

(1) a gRNA spacer;
(2) a gRNA scaffold;
(3) a heterologous object sequence; and
(4) a primer binding site (PBS) sequence.

One or more template RNAs described in Tables 1A-4D can be tested as described in this example. The heterologous object sequences and PBS sequences were designed to correct the

PAH mutation in a landing pad by replacing a “T” nucleotide with a “C” nucleotide at the mutation site via gene editing, to reverse a R408W mutation in the corresponding protein.

A cell line is created to have a “landing pad” or a stable integration that mimics a region of the PAH gene that contains the R408W mutation site and flanking sequences. The DNA for the landing pad is chemically synthesized and cloned into the pLenti-N-tGFP vector. The cloned landing pad sequence in the lentiviral expression vector is confirmed and the sequence is verified by Sanger sequencing of the landing pad. The sequence verified plasmids (9µg) along with the lentiviral packaging mix (9µg, Biosettia) are transfected using Lipofectamine2000™ according to the manufacturer instructions into a packaging cell line, LentiX-293T (Takara Bio). The transfected cells are incubated at 37˚C, 5% CO_2 for 48 hours (including one medium change at 24hrs) and the viral particle containing medium is collected from the cell culture dish. The collected medium is filtered through a 0.2 µm filter to remove cell debris and is prepared for transduction of HEK293T cells. The virus-containing medium is diluted in DMEM and mixed with polybrene to prepare a dilution series for transduction of HEK293T cells where the final concentration of polybrene is 8 µg/ml. The HEK293T cells are grown in virus containing medium for 48 hours and then split with fresh medium. The split cells are grown to confluence and transduction efficiency of the different dilutions of virus is measured by GFP expression via flow cytometry and ddPCR detection of the genomic integrated lentivirus that contained GFP and the PAH landing pads.

A gene modifying system comprising a (i) compatible gene modifying polypeptide described herein, e.g., having: an NLS of Table 11, a compatible Cas9 domain having a sequence of Table 8 (e.g., SpyCas9-SpRY), a linker of Table 10, an RT sequence of Table 6 (e.g., MLVMS_P03355_PLV919), and a second NLS of Table 11 and (ii) a template RNA of any of Tables 1A-4D (e.g., a template RNA of ID #1) is transfected into the HEK293T landing pad cell line. The gene modifying polypeptide and the template RNAs are delivered by nucleofection in RNA format. Specifically, 1µg of gene modifying polypeptide mRNA is combined with 10µM template RNAs. The mRNA and template RNAs are added to 25µL SF buffer containing 250,000 HEK293T landing pad cells and cells are nucleofected using program DS-150. After nucleofection, are were grown at 37˚C, 5% CO_2 for 3 days prior to cell lysis and genomic DNA extraction. To analyze gene editing activity, primers flanking the PAH mutation site are used to amplify across the locus. Amplicons are analyzed via short read sequencing using an Illumina

MiSeq. In some embodiments, the assay will indicate that at least 5%, 10%, 20%, 30%, 40%, or 50% of copies of the PAH gene in the sample are converted to the desired wild-type sequence.

Example 2: Gene modifying polypeptide selection by pooled screening in HEK293T & U2OS cells

This example describes the use of an RNA gene modifying system for the targeted editing of a coding sequence in the human genome. More specifically, this example describes the infection of HEK293T and U2OS cells with a library of gene modifying candidates, followed by transfection of a template guide RNA (tgRNA) for *in vitro* gene modifying in the cells, e.g., as a means of evaluating a new gene modifying polypeptide for editing activity in human cells by a pooled screening approach.

The gene modifying polypeptide library candidates assayed herein each comprise: 1) a *S. pyogenes* (Spy) Cas9 nickase containing an N863A mutation that inactivates one endonuclease active site; 2) one of the 122 peptide linkers depicted at **Table 10**; and 3) a reverse transcriptase (RT) domain from **Table 6** of retroviral origin. The particular retroviral RT domains utilized were selected if they were expected to function as a monomer. For each selected RT domain, the wild-type sequences were tested, as well as versions with point mutations installed in the primary wild-type sequence. In particular, 143 RT domains were tested, either wild type or containing various mutations. In total, 17,446 Cas-linker-RT gene modifying polypeptides were tested.

The system described here is a two-component system comprising: 1) an expression plasmid encoding a human codon-optimized gene modifying polypeptide library candidate within a lentiviral cassette, and 2) a tgRNA expression plasmid expressing a non-coding tgRNA sequence that is recognized by Cas and localizes it to the genomic locus of interest, and that also templates reverse transcription of the desired edit into the genome by the RT domain, driven by a U6 promoter. The lentiviral cassette comprises: (i) a CMV promoter for expression in mammalian cells; (ii) a gene modifying polypeptide library candidate as shown; (iii) a self-cleaving T2A polypeptide; (iv) a puromycin resistance gene enabling selection in mammalian cells; and (v) a polyA tail termination signal.

To prepare a pool of cells expressing gene modifying polypeptide library candidates, HEK293T or U2OS cells were transduced with pooled lentiviral preparations of the gene modifying candidate plasmid library. HEK293 Lenti-X cells were seeded in 15 cm plates ($12x10^6$ cells) prior to lentiviral plasmid transfection. Lentiviral plasmid transfection using the Lentiviral

Packaging Mix (Biosettia, 27 ug) and the plasmid DNA for the gene modifying candidate library (27 ug) was performed the following day using Lipofectamine 2000 and Opti-MEM media according to the manufacturer's protocol. Extracellular DNA was removed by a full media change the next day and virus-containing media was harvested 48 hours after. Lentiviral media was concentrated using Lenti-X Concentrator (TaKaRa Biosciences) and 5 mL lentiviral aliquots were made and stored at -80°C. Lentiviral titering was performed by enumerating colony forming units post Puromycin selection. HEK293T or U2OS cells carrying a BFP-expressing genomic landing pad were seeded at $6x10^7$ cells in culture plates and transduced at a 0.3 multiplicity of infection (MOI) to minimize multiple infections per cell. Puromycin (2.5 ug/mL) was added 48 hours post infection to allow for selection of infected cells. Cells were kept under puromycin selection for at least 7 days and then scaled up for tgRNA electroporation.

To determine the genome-editing capacity of the gene modifying library candidates in the assay, infected BFP-expressing HEK293T or U2OS cells were then transfected by electroporation of 250,000 cells/well with 200 ng of a tgRNA (either g4 or g10) plasmid, designed to convert BFP to GFP, at sufficient cell count for >1000x coverage per library candidate.

The g4 tgRNA (5′ to 3′) is as follows: 20 nucleotide spacer region (GCCGAAGCACTGCACGCCGT; SEQ ID NO: 11,011), a scaffold region (GTTTTAGAGCTAGAAATAGCAAGTTAAAATAAGGCTAGTCCGTTATCAACTTGAAAAAGTGGCACCGAGTCGGTGC; SEQ ID NO: 11,012), the template region encoding the single base pair substitution to change BFP to GFP (**bold**) and a PAM inactivation that introduces a synonymous point mutation in the SpyCas9 PAM (NGG to NCG) that prevents re-engagement of the gene modifying polypeptide upon completion of a functional gene modifying reaction (underline) (ACCCTGAC<u>G</u>**T**ACG; SEQ ID NO: 11,013), and the 13 nucleotide PBS (GCGTGCAGTGCTT; SEQ ID NO: 11,014).

Similarly, the g10 tgRNA (5′ to 3′) is as follows: 20 nucleotide spacer region (AGAAGTCGTGCTGCTTCATG; SEQ ID NO: 11,015), a scaffold region (GTTTTAGAGCTAGAAATAGCAAGTTAAAATAAGGCTAGTCCGTTATCAACTTGAAAAAGTGGCACCGAGTCGGTGC; SEQ ID NO: 11,016), the template region encoding the single base pair substitution to change BFP to GFP (**bold**) and a PAM inactivation that introduces a synonymous point mutation in the SpyCas9 PAM (NGG to NGA) that prevents re-engagement of the gene modifying polypeptide upon completion of a functional gene modifying

reaction (underline)
(ACCCTGACCTACGGCGTGCAGTGCTTCGGCCGCTACCCCGATCACAT; SEQ ID NO: 11,017), and 13 nucleotide PBS (GAAGCAGCACGAC; SEQ ID NO: 11,018).

To assess the genome-editing capacity of the various constructs in the assay, cells were sorted by Fluorescence-Activated Cell Sorting (FACS) for GFP expression 6-7 days post-electroporation. Cells were sorted and harvested as distinct populations of unedited (BFP+) cells, edited (GFP+) cells and imperfect edit (BFP-, GFP-) cells. A sample of unsorted cells was also harvested as the input population to determine enrichment during analysis.

To determine which gene modifying library candidates have genome-editing capacity in this assay, genomic DNA (gDNA) was harvested from sorted and unsorted cell populations, and analyzed by sequencing the gene modifying library candidates in each population. Briefly, gene modifying sequences were amplified from the genome using primers specific to the lentiviral cassette, amplified in a second round of PCR to dilute genomic DNA, and then sequenced using Oxford Nanopore Sequencing Technology according to the manufacturer's protocol.

After quality control of sequencing reads, reads of at least 1500 and no more than 3200 nucleotides were mapped to the gene modifying polypeptide library sequences and those containing a minimum of an 80% match to a library sequence were considered to be successfully aligned to a given candidate. To identify gene modifying candidates capable of performing gene editing in the assay, the read count of each library candidate in the edited population was compared to its read count in the initial, unsorted population. For purposes of this pooled screen, gene modifying candidates with genome-editing capacity were selected as those candidates that were enriched in the converted (GFP+) population relative to unsorted (input) cells and wherein the enrichment was determined to be at or above the enrichment level of a reference (Element ID No: 17380).

A large number of gene modifying polypeptide candidates were determined to be enriched in the GFP+ cell populations. For example, of the 17,446 candidates tested, over 3,300 exhibited enrichment in GFP+ sorted populations (relative to unsorted) that was at least equivalent to that of the reference under similar experimental conditions (HEK293T using g4 tgRNA; HEK293T cells using g10 tgRNA; or U2OS cells using g4 tgRNA), shown in Table D. Although the 17,446 candidates were also tested in U2OS cells using g10 tgRNA, the pooled screen did not yield

candidates that were enriched in the converted (GFP+) population relative to unsorted (input) cells under that experimental condition; further investigation is required to explain these results.

Table D. Combinations of linker and RT sequences screened. The amino acid sequence of each RT in this table is provided in Table 6.

Example 3: Quantifying activity of a gene editing polypeptide and template for rewriting the endogenous FAH locus achieved in primary mouse hepatocytes

This example demonstrates the use of a gene modifying system containing a gene modifying polypeptide and a template RNA, to convert an A nucleotide to a G nucleotide in the endogenous *Fah* locus in mouse primary hepatocytes derived from a Fah5981SB mouse. The Fah5981SB mouse model harbors a G to A point mutation in the last nucleotide of exon 8 of the *Fah* gene, leading to aberrant mRNA splicing and subsequent mRNA degradation, without the production of Fah protein and, and thus serves as a mouse model of hereditary tyrosinemia type I.

In this example, the template RNA contained:

(1) a gRNA spacer;

(2) a gRNA scaffold;

(3) a heterologous object sequence; and

(4) a primer binding site (PBS) sequence.

More specifically, the template RNA (including chemical modification pattern) comprised the following sequences:

Underlining indicates the residue that differs between the nickase and wild-type sequences.

The gene modifying system comprising the gene modifying polypeptides listed above and the template RNA described above were transfected into primary mouse hepatocytes. The gene modifying polypeptide and the template RNA were delivered by nucleofection in the RNA format. Specifically, 4 µg of gene modifying polypeptide mRNA were combined with 10 µg of chemically synthesized template RNA in 5 µL of water. The transfection mix was added to 100,000 mouse primary hepatocytes in Buffer P3 [Lonza], and cells were nucleofected using program DG-138. After nucleofection, cells were grown at 37˚C, 5% CO_2 for 3 days prior to cell lysis and genomic DNA extraction. To analyze gene editing activity, primers flanking the target insertion site locus were used to amplify across the locus. Amplicons were analyzed via short read sequencing using an Illumina MiSeq. Conversion of terminal A to G sequence in exon 8 of *fah* gene indicates successful editing.

As shown in FIG. 2, for FAH2 templates, perfect rewrite levels (conversion of A to G with no unwanted mutations detected) of 4-8% were detected with RNAV209 but not with RNAV214. Indel levels of 4.4 to 6.6% were observed with RNAV209. Furthermore, the amount of WT *Fah* mRNA was measured using quantitative RT-PCR using primers that bind to exons 7 and 8. As shown in FIG. 3, FAH2 templates result in an increase in the abundance of *Fah* mRNA relative to WT by up to 12% when FAH2 template is tested with RNAV209 mRNA. These results demonstrate the use of a gene modifying system to reverse a mutation in the *Fah* gene, resulting in partial restoration of the expression of wild-type *Fah* mRNA.

Example 4: Quantifying activity of a gene editing polypeptide and template in vivo for rewriting the endogenous FAH locus achieved in mouse liver

This example demonstrates the use of a gene modifying system containing a gene modifying polypeptide and a template RNA, to convert an A nucleotide to a G nucleotide in the Fah5981SB mouse model into the endogenous *Fah* locus in mouse liver. The Fah5981SB mouse model harbors a G to A point mutation in the last nucleotide of exon 8 of the *Fah* gene, leading to aberrant mRNA splicing and subsequent mRNA degradation, without the production of Fah protein and serves as a mouse model of hereditary tyrosinemia type I.

In this example, the template RNA contained:

(1) a gRNA spacer;
(2) a gRNA scaffold;
(3) a heterologous object sequence; and
(4) a primer binding site (PBS) sequence.

More specifically, the template RNA comprised the following sequences:

FAH1_R14_P12_Heavy RNACS048-001

The gene modifying polypeptides tested comprised a sequence of: RNAV209 and RNAV214, the sequences of which are each provided in Example 3.

The gene modifying system comprising the gene modifying polypeptides and the template RNA described above was formulated in LNP and delivered to mice. Specifically, 2mg/kg of total RNA equivalent formulated in LNPs, combined at 1:1 (w/w) of template RNA and mRNA, were dosed intravenously in 7 to 9-week-old, mixed gender Fah5981SB mice. Six hours or 6 days post-dosing, animals were sacrificed, and their liver collected for analyses. To determine the expression distribution of the gene modifying polypeptide in the liver, 6-hr liver samples were subjected to immunohistochemistry using an anti-Cas9 antibody. Upon staining, quantification of Cas9-positive hepatocytes was determined by QuPath Markup. As shown in FIG.4, the expression of the gene modifying polypeptide was observed in 82-91% of hepatocytes.

To analyze gene editing activity, primers flanking the target insertion site locus were used to amplify across the locus in the genomic DNA of liver samples collected 6 days post-dosing. Amplicons were analyzed via short read sequencing using an Illumina MiSeq. Conversion of an A nucleotide to a G nucleotide indicates successful editing. As shown in FIG.5, perfect rewrite

levels (conversion of A to G with no unwanted mutations detected) of 0.1% - 1.9% were detected across the different groups. Indel levels were in the range of 0.2% - 0.4%.

To determine the phenotypic correction caused by the gene editing activity, the restoration of wild-type FAH mRNA was determined by real-time qRT-PCR, and the restoration of Fah protein expression determined by immunohistochemistry using an anti-Fah antibody. As shown in FIG.6, wild-type mRNA restoration of 0.1% - 6%, relative to littermate heterozygous mice, was detected across the different groups. As shown in FIG. 7, Fah protein was detected in 0.1% - 7% of liver cross-sectional area across the different groups. These results demonstrate the use of a gene modifying system to reverse a mutation in the *Fah* gene in an *in vivo* mouse model for hereditary tyrosinemia type I, resulting in partial restoration of expression of wild-type *Fah* mRNA and Fah protein.

Example 5. Gene editing at the TTR locus in an in vivo mouse model

This Example demonstrates successful delivery of an mRNA and guide using Cas9-mediated gene editing using the protospacer sequence ACACAAAUACCAGUCCAGCG (SEQ ID NO: 37641) that targets the TTR locus using a gene modifying polypeptide and RNA in a C57Blk/6 mouse.

RNAs were prepared as follows. An mRNA encoding a gene modifying polypeptide having the sequence shown in Table 5A1 below was produced by in vitro transcription and the purified mRNA was dissolved in 1 mM sodium citrate, pH 6, to a final concentration of RNA of 1-2 mg/mL. Similarly, a guide RNA having a sequence shown in Table 5A1 below was produced by chemical synthesis and dissolved in water or aqueous buffer, to a final concentration of RNA of 1-2 mg/mL.

Lipid nanoparticle (LNP) components (ionizable lipid, helper lipid, sterol, PEG) were dissolved in 100% ethanol with the lipid component molar ratios of 47:8:43.5:1.5, respectively. RNA (guide and mRNA) was combined in a 1:1 weight ratio and diluted to a concentration of 0.05-0.2 mg/mL in sodium acetate buffer, pH 5. RNA was formulated into distinct LNPs with a lipid amine to total RNA phosphate (N:P) molar ratio of 4.0. The LNPs were formed by microfluidic or turbulent mixing of the lipid and RNA solutions. A 3:1 ratio of aqueous to organic solvent was maintained during mixing using differential flow rates. After mixing, the LNPs were diluted, collected and buffer exchanged into 50 mM Tris, 9% sucrose buffer using tangential flow filtration. Formulations were concentrated to 1.0 mg/mL or higher then filtered through 0.2 μm sterile filter. The final LNP were stored at −80˚C until further use.

The LNP formulations were delivered intravenously by bolus tail vein injection to C57Blk/6 mice that were approximately 8 weeks old at concentrations ranging from 1-0.1 mg/kg. The expression of the Cas9-RT was measured by 6 hours after injection by euthanizing animals and collecting livers during necropsy. Animals were euthanized at 5 days after injection where liver was collected upon necropsy to which the activity of gene editing of the TTR locus was assessed. Expression of the Cas9-RT gene editing polypeptide in liver was measured by Western blot where Cas9 was detected by a mouse monoclonal antibody (7A9-3A3, Cell Signaling Technology) and GAPDH (Cell Signaling Technology) was used as a loading control. (FIG. 8). Editing of the TTR locus was quantified by Sanger sequencing followed by TIDE analysis of an amplicon of the TTR locus near the binding site of the protospacer. Editing of the

TTR locus was observed, as shown in FIG. 9. TTR protein levels in serum were quantified by an ELISA using a standard curve (Aviva Biosciences). TTR protein levels in serum declined in treated animals, as shown in FIG. 10. These experiments demonstrate that the Cas9-RT polypeptide can be expressed *in vivo*, and can edit the TTR locus, resulting in a decrease in TTR protein levels in serum.

Example 6. Gene editing at the TTR locus in an in vivo cynomolgus macaque model

This Example demonstrates successful delivery of an mRNA and guide using Cas9-mediated gene editing using the protospacer sequence ACACAAAUACCAGUCCAGCG (SEQ ID NO: 37641) that targets the TTR locus using a gene modifying polypeptide and RNA in a cynomolgus model.

RNAs were prepared as follows. An mRNA encoding a gene modifying polypeptide having the sequence shown in Table 6A1 below was produced by in vitro transcription and the purified mRNA was dissolved in 1 mM sodium citrate, pH 6, to a final concentration of RNA of 1-2 mg/mL. Similarly, a guide RNA having a sequence shown in Table 6A1 below was produced by chemical synthesis and dissolved in water or aqueous buffer, to a final concentration of RNA of 1-2 mg/mL.

Lipid nanoparticle (LNP) components (ionizable lipid, helper lipid, sterol, PEG) were dissolved in 100% ethanol with the lipid component molar ratios of 47:8:43.5:1.5, respectively. RNA (guide and mRNA) was combined in a 1:1 weight ratio and diluted to a concentration of 0.05-0.2 mg/mL in sodium acetate buffer, pH 5. RNA was formulated into distinct LNPs with a lipid amine to total RNA phosphate (N:P) molar ratio of 4.0. The LNPs were formed by microfluidic or turbulent mixing of the lipid and RNA solutions. A 3:1 ratio of aqueous to organic solvent was maintained during mixing using differential flow rates. After mixing, the LNPs were diluted, collected and buffer exchanged into 50 mM Tris, 9% sucrose buffer using tangential flow filtration. Formulations were concentrated to 1.0 mg/mL or higher then filtered through 0.2 μm sterile filter. The final LNP were stored at −80˚C until further use. The LNP formulations were delivered intravenously by infusion over the course of 1 hour at 2 mg/kg where the volume of the infusion was 5 ml/kg. Cynomolgus macaques from mainland Asia were given dexamethasone 2 mg/kg bolus via intramuscular injection 1.5-2 h prior to intravenous infusion using a syringe pump. Animals were monitored after infusion and the expression of the Cas9-RT was measured by laparoscopic biopsies taken from the liver 8-12 h, 24 h, and 48 h after infusion. Animals were euthanized 14 days after infusion and liver was harvested by dividing the organ up into 8 different segments to which the activity of gene editing of the TTR locus was assessed. Expression of the Cas9-RT gene editing polypeptide in liver was quantified by capillary electrophoresis western blot using the ProteinSimple Jess system (bio-techne) where Cas9 was detected by a mouse monoclonal antibody (7A9-3A3, Cell Signaling Technology). Relative expression of the Cas9-RT gene editing polypeptide was measured by an area under curve analysis, as shown in FIG. 11. Editing of the TTR locus was quantified by amplicon-sequencing of the TTR locus near the binding site of the protospacer. Editing of the TTR locus was observed, as shown in FIG. 12. These experiments demonstrate that the Cas9-RT polypeptide can be expressed *in vivo* in a non-human primate model and can edit the TTR locus.

Example 7: Evaluating rewrite efficiency of exemplary template RNAs and second strand-nicking gRNAs with an exemplary gene modifying polypeptide in correcting an F263S mutation in a murine Pah gene in murine hepatocyte cells

This example describes the use of exemplary gene modifying systems containing either of two gene modifying polypeptides and template RNAs comprising varied lengths of

heterologous object sequences and PBS sequences to quantify the activity of template RNAs for correction of an F263S mutation (corresponding to a T835C base change) in the murine ***Pah*** gene. In this example, a template RNA contained:

(1) a gRNA spacer;
(2) a gRNA scaffold;
(3) a heterologous object sequence; and
(4) a primer binding site (PBS) sequence.

Exemplary template RNAs generated are given in Table E1. Two different versions of each template RNA were produced and tested (EM and HM), one with a first level and distributions of nucleotide modifications (e.g., phosphorothioate linkages denoted by an asterisk and/or 2'-O-methyl groups denoted by an 'm' preceding a nucleotide) and one with a second level and distribution.

In Examples 7-8, unless otherwise noted the HM version of a template RNA was used in the described experiments.

In this example, exemplary gene modifying polypeptide RNAV209 was examined. Gene modifying polypeptide 1 (RNAV209) comprised two NLS sequences (e.g., a c-Myc NLS and an SV40 NLS), an exemplary endonuclease domain comprising nCas9 which comprised an N863A mutation relative to wildtype Cas9, an exemplary RT domain comprising a MoMLV RT sequence (comprising D200N, T306K, W313F, T330P, and L603W mutations relative to a wildtype MoMLV RT sequence), and an exemplary flexible linker connecting the RT and endonuclease domains and comprising the amino acid sequence of SEQ ID NO: 6. The amino acid sequence of RNAV209 is given by SEQ ID NO: 30477.

ESPKKKAKVE (SEQ ID NO: 30477)

Mouse primary hepatocytes were prepared for administration of a gene modifying system as follows. The liver from animals under anesthesia were cannulated at the vena cava and perfused with 1 mg/mL Liberase digestion buffer. Upon digestion, the entire liver was dissected, cells were released into suspension in media and remaining connective tissue was eliminated by filtration with 70 µm cell strainer. Viable hepatocytes were further purified from dead cells and non-parenchymal cells by centrifugation in a 40% Percoll solution.

A gene modifying system comprising a (i) RNAV209 gene modifying polypeptide described herein, and (ii) a template RNA of any of Table E1 was nucleofected into prepared mouse primary hepatocytes in RNA format. Specifically, 4 µg of gene modifying polypeptide mRNA was combined with 10 µg of template RNAs in a total volume of 5 µL. The mRNA and template RNAs are added to 20µL P3 buffer containing 100,000 primary hepatocytes cells and cells were nucleofected. After nucleofection, cells were grown at 37˚C, 5% CO_2 for 3 days prior to cell lysis and genomic DNA extraction. To analyze gene editing activity, primers flanking the *Pah* mutation site were used to amplify across the locus. Amplicons were analyzed via short read sequencing using an Illumina MiSeq. **FIG. 13** shows a graph of the rewriting rate (the rate at which the target mutation was corrected) in primary mouse hepatocytes nucleofected with the indicated template RNA and RNAV209 gene modifying polypeptide as measured by Amp-SEQ. Rewriting was seen with a number of exemplary template RNAs.

Higher rewriting rates can increase the impact of administered gene modifying systems and could decrease the amount of a gene modifying system required to achieve a therapeutic effect. Generation of a second nick to the second strand proximal to the template RNA specified nick may increase rewriting rate, e.g., by biasing cellular DNA repair toward incorporation of the mutation correction. To test the ability of a second nick to increase rewriting, exemplary second strand-targeting gRNAs were screened by administration with the top performing template RNA from **FIG. 13** (mPKU5_R11_P8) and RNAV209 to mouse primary hepatocytes prepared as described above (**FIG. 14**).

Table E2. Exemplary second strand-targeting gRNAs (ngRNAs)

RNA CS	Description	Sequence	SEQ ID NO
RNA CS2100	mPKU_ngRNA1	UAUAAAAAGCCUUGAGUUUUGUUUUAGAGCUAGAAAUAGCAAGUUAAAAUAAGGCUAGUCCGUUAUCAACUUGAAAAAGUGGCACCGAGUCGGUGCUUUU	30478
RNA CS2101	mPKU_ngRNA5	CUGUCGUCUCGAGAUUUCUUGUUUUAGAGCUAGAAAUAGCAAGUUAAAAUAAGGCUAGUCCGUUAUCAACUUGAAAAAGUGGCACCGAGUCGGUGCUUUU	30479

The presence of second strand-targeting gRNAs increased the rewriting activity of the exemplary RNAV209/ mPKU5_R11_P8 gene modifying system. Two second strand-targeting gRNAs were selected for further evaluation: ngRNA1 (specifying a second strand nick more than 100 bp from the mutation to be corrected) and ngRNA5 (specifying a second strand nick less than 40 bp from the mutation to be corrected). Template RNAs from Table E1 were combined with RNAV209 and either ngRNA1 or ngRNA5 and rewrite efficiency was evaluated as above (**FIG. 15**). ngRNA5 enhanced rewrite efficiency relative to the absence of second strand-targeting gRNA when combined with a number of template RNAs.

These results demonstrate that an exemplary gene modifying system comprising RNAV209 and any of a variety of template RNAs can correct a mutation in a murine PAH gene in murine hepatocytes, and that the efficiency of rewriting can be enhanced by the addition of a second nick specified by a second strand-nicking gRNA.

Example 8: Comparing exemplary template RNAs and gene modifying polypeptides that correct an F263S mutation in a murine Pah gene in murine model animals

This example describes the use of exemplary gene modifying systems containing either of two gene modifying polypeptides and template RNAs comprising varied lengths and compositions of heterologous object sequences and PBS sequences to quantify the activity of template RNAs for correction of an F263S mutation (corresponding to a T835C base change) in the murine *Pah* gene. The enhancing effect of inclusion of a second strand-targeting gRNA was also examined. In this example, a template RNA contained:

(1) a gRNA spacer;

(2) a gRNA scaffold;

(3) a heterologous object sequence; and

(4) a primer binding site (PBS) sequence.

Exemplary template RNAs tested were template RNAs RNACS1855, RNACS1862, RNACS2103, RNACS2104, and RNACS2099, shown in Table E1. The exemplary second strand-targeting gRNA was RNACS2101, shown in Table E2.

Exemplary gene modifying polypeptide RNAV209 was compared to exemplary gene modifying polypeptide 2 (RNAIVT338). RNAIVT338 comprised two NLS sequences (e.g., a c-Myc NLS and an SV40 NLS), an exemplary endonuclease domain comprising Cas9, an exemplary RT domain comprising an AVIRE RT sequence, and an exemplary linker between the RT and endonuclease domains and comprising the amino acid sequence of SEQ ID NO: 217. The amino acid sequence of RNAIVT338 is given by SEQ ID NO: 30480.

SPKKKAKVE (SEQ ID NO: 30480)

The gene modifying system comprising either RNAV209 or RNAIVT338 gene modifying polypeptide and a template RNA described above was formulated in LNP and delivered to mice. Specifically, approximately 1.6 or 2.4 mg/kg of total RNA equivalent formulated in LNPs, combined at 1:1 (w/w) of template RNA and mRNA, were dosed intravenously in 8 to 10-week-old, mixed gender ENU2 mice (0.8 mg/kg each of template RNA and mRNA, optionally with an additional 0.8 mg/kg of ngRNA for second strand-targeting experiments) in a 10 ml/kg bolus. Mice were administered a first dose at time 0 (t = 0), and a second dose at t = 24 hours. Six hours or 7 days post-dosing (as used herein post-dosing refers to time since the first dose), animals were sacrificed, and their liver and plasma collected for analyses. To determine the expression distribution of the gene modifying polypeptide in the liver, 6-hr liver samples were subjected to immunohistochemistry using an anti-Cas9 antibody. Upon staining, quantification of Cas9-positive hepatocytes was determined by QuPath Markup. As shown in **FIG. 16**, the expression of the gene modifying polypeptide was observed in 70-80% of hepatocytes. 6-hour liver samples were further analyzed by Western blot using an anti-Cas9 antibody. As shown in **FIG. 17**, expression of the gene modifying polypeptide was observed in liver from all treated animals. These results show that both RNAV209 and RNAIVT338 gene modifying polypeptides are expressed in murine liver at 6 hours post-dosing.

7-day plasma samples were analyzed by LC/MS to determine the level of phenylalanine present. ENU2 mice harbor a mutation in the murine PAH gene that inactivates the PAH enzyme, resulting in sharply higher Phe levels in plasma than healthy wildtype mice.

Phenylalanine was extracted from mouse plasma using protein precipitation and then analyzed by a LC-MS/MS system equipped with a Shimadzu Nexera UPLC (LC-40) coupled to a Sciex API 7500 mass spectrometer. Surrogate analyte (13C2,15N-Phenylalanine) was used for phenylalanine quantitation. Equivalence of ionization for naturally occurring and surrogate compounds was established prior to and after analytical run. Data were collected in the positive ion mode with three MRM transitions, 169.1 to 123.1 (13C2,15N-Phenylalanine), 166.1 to 120.1(Phenylalanine) and 172.1 to 126.0 (13C6-Phenylalanine, internal standard). Extracted

samples were injected onto an Acquity UPLC BEH C18 column (1.7µm, 2.1x50 mm) and eluted using a gradient of 0% to 15% of mobile phase B at a flow rate of 0.8 mL/min with a total run time of 3 min per injection. Mobile phase A is 100:2:0.1 H2O:Formic acid (FA): Trifluoroacetic acid (TFA) and mobile phase B is 95:5:2:0.1 ACN:H2O:FA:TFA. Data were processed using Sciex OS software.

The results showed that Phe levels decreased in plasma from all treated mice, consistent with correction of the PAH deactivating point mutation using either gene modifying polypeptide and either of the template RNAs examined (**FIG. 18**). Treatment with LNP containing RNAIVT338 decreased Phe levels more than treatment with LNP containing RNAV209, with RNAIVT338 decreasing Phe levels by approximately 65% relative to saline compared to RNAV209 decreasing Phe levels by approximately 40%. Similarly, treatment using template RNACS1855 decreased Phe levels more than treatment with template RNACS1862, independent of which gene modifying polypeptide was administered. RNACS1855 contains a shorter reverse transcriptase binding sequence (11 nucleotides) than template RNACS1862 (15 nucleotides).

7-day liver samples were further analyzed using Amp-Seq to determine % rewriting and % INDEL in target liver cells (**FIGs. 19A** and **FIG. 19B**). To analyze gene editing activity, primers flanking the target insertion site locus were used to amplify across the locus in the genomic DNA of liver samples. Amplicons were analyzed via short read sequencing using an Illumina MiSeq. Conversion of a C nucleotide to a T nucleotide at position 835 in the PAH gene indicates successful editing. Rewriting was observed from all treated mice, demonstrating that the gene modifying systems tested successfully corrected the PAH mutation (FIG. 19A). Treatment with LNP containing RNAIVT338 resulted in a higher rewrite % than treatment with LNP containing RNAV209, with approximately twice the rewrite % observed when using RNAIVT338 relative to RNAV209. Similarly, treatment using template RNACS1855 resulted in a higher rewrite % than treatment with template RNACS1862, independent of which gene modifying polypeptide was used. Treatment with LNP containing RNAIVT338 resulted in a lower INDEL % than treatment with LNP containing RNAV209, with almost half the INDEL % observed when using RNAIVT338 relative to RNAV209 (FIG. 19B). Treatment using template RNACS1855 resulted in a lower INDEL % than treatment with template RNACS1862, independent of which gene modifying polypeptide was used.Based on RNAIVT338’s improved performance over

RNAV209, additional template RNAs were tested in combination with RNAIVT338. ENU2 mice were treated as described above using a gene modifying system comprising RNAIVT338 and one of template RNAs RNACS1855, RNACS1862, RNACS2103, RNACS2104, and RNACS2099, and liver and plasma samples were taken from sacrificed mice at 7 days post-dosing (**FIGs. 20A, 20B,** and **20C**). Rewriting was observed in all treated samples, with strong correlation between % rewriting in liver samples and Phe level reduction in plasma samples. INDEL % was much lower (approximately 25 to 35 times lower) than rewriting %, and correlated with rewriting % level (FIG. 20C). The results demonstrate that rewriting a disease-associated mutation using a gene modifying system containing RNAIVT338 can correct the disease-associated mutation and achieve the desired therapeutic effect (e.g., reduction in Phe level), and that RNAIVT338 achieves rewriting with a number of template RNAs. The results further demonstrate that the rewriting occurs with low levels of INDEL generation.

To determine whether second strand-nicking can enhance rewriting efficiency and improve Phe-reducing therapeutic effect, ENU2 mice were treated as described above with exemplary gene modifying system containing RNAIVT338, template RNA, as well as ngRNA5 which directs a second strand nick less than 40 bp from the target PAH mutation, and liver and plasma samples were analyzed as described above (**FIGs. 21A and 21B**). Administering a gene modifying system including a second strand-targeting gRNA increased % rewriting in liver and decreased plasma Phe levels relative to gene modifying systems not containing a second strand-targeting gRNA. Over 40% of the liver cells sampled contained the rewrite modification after mice were treated with a gene modifying system containing gene modifying polypeptide RNAIVT338 and an exemplary template RNA and second strand nicking gRNA (FIG. 21A), and this was accompanied by serum Phe levels of approximately 100 μM, physiologically normal for mice (FIG. 21B). Indel percent, while measurably higher when the second strand-targeting gRNA was included, remained low relative to rewriting percent. These results show adding a second strand nick proximal to the mutation to be corrected (e.g., biasing cellular DNA repair to favor correction of the mutation) can increase rewriting and substantially increase the therapeutic

effect. These results further show that unintended modifications (e.g., indels) are not significantly increased by second strand nicking.

Across *in vivo* murine samples, percent rewriting observed in liver samples should correlate inversely with Phe plasma levels if a gene modifying system is effectively correcting a PAH-inactivating, hyperphenylalaninemia (HPA)-inducing mutation. To confirm this, Phe level in plasma samples was plotted over % rewriting for all plasma and liver samples obtained from treated ENU2 mice (**FIG. 22**). The results show a clear inverse correlation; as % rewriting increases, plasma Phe levels decrease. Plotted as dotted lines are literature-recognized physiologically normal Phe levels and mild-HPA Phe levels in mice (*see, e.g.,* Ahmed et al. Mol Ther Methods Clin Dev. 2020 Mar 13;17:568-580 or Bruinenberg et al. Front Behav Neurosci. 2016; 10: 233). The results show that treatment with nearly all combinations of gene modifying polypeptides, template RNAs, and second strand-targeting gRNAs reduce Phe levels to below mild HPA levels and to normal Phe levels in many cases.

Example 9: Evaluating safety and efficacy of exemplary template RNAs and gene modifying polypeptides that insert a silent mutation in a primate PAH gene in non-human primate model animals

This example describes the use of exemplary gene modifying systems containing an exemplary gene modifying polypeptide (e.g., RNAIVT338, described above), exemplary template RNA (e.g., described in Tables 4A-4D), and optionally an exemplary second strand-nicking gRNA (e.g., described in Tables 4A-4D) to demonstrate the safety of the gene modifying systems, translation activity of the gene modifying polypeptide, and rewriting activity in a group of non-human primates (NHPs). In some embodiments, the NHPs are Cynomolgus macaques. In some embodiments, the NHPs are Rhesus macaques.

One, two, or more studies are performed. The studies treat NHPs using exemplary gene modifying systems and determine the safety of administration of the systems and/or evaluate the efficacy of the gene modifying system (e.g., percent rewriting, writing accuracy (e.g., indel and imperfect rewriting), and/or phenotypic correction (e.g., PAH protein/mRNA expression and/or plasma Phe level)).

NHPs are distributed into two treated groups, with at least 3 individuals per treated group. Pre-dosing liver biopsy samples are taken at approximately 7 days pre-dosing. Doses of gene modifying system containing mRNA encoding RNAIVT338, exemplary template RNA, and optionally exemplary second strand-nicking gRNA are formulated in LNPs, combined at 1:1 (w/w) of template RNA and mRNA (and optionally 1:1:1 w/w/w of template RNA, mRNA, and gRNA). On Day 1, a single dose is administered intravenously at 3 mg/kg. A single-dose liver biopsy sample is collected from treated individuals one week after the single dose (Day 8). One week after the single-dose liver biopsy sample is taken, the multi-dose phase of the study begins, with two or more (e.g., three) additional doses administered on an alternating day schedule (e.g., on days 15, 17, and 19). A multi-dose liver biopsy sample is collected from treated individuals one week after the last dose of the multi-dose phase (e.g., day 26).

Liver samples are analyzed by Amp-Seq to determine % rewriting, LC/MS to determine Phe levels, and/or immunohistochemistry (e.g., in situ hybridization and/or Western blot) to determine expression of the exemplary gene modifying polypeptide. Plasma samples are obtained from blood draws at each biopsy time point, as well as at shorter time points (e.g., less than 7 days post-dosing). Plasma samples are analyzed, e.g., by LC/MS, for Phe levels. Rewriting will be observed in liver cells after a single dose, with increasing rewriting % observed after multiple doses are administered. Plasma Phe levels will be observed to decrease after a single dose, with more significant decreases observed after multiple doses are administered and correlating with rewriting %.

Example 10: Demonstrating Use of Different Exemplary Template RNA Spacers to Target Macaca fascicularis PAH gene

This example describes the use of exemplary gene modifying systems containing a gene modifying polypeptide and template RNAs comprising one of four different gRNA spacer sequences combined with a variety of heterologous object sequences and PBS sequences to induce a series of phenylketonuria relevant genetic alterations in HEK293T cells modified to contain a ***Macaca fascicularis*** PAH gene. This example demonstrates gene modification to:

(1) Introduce a silent C to A mutation in the codon homologous to that encoding human R408 (CtoA)

(2) Introduce the C to A mutation of (1) and additionally a PAM/seed killing mutation that inhibits retargeting by the gene modifying polypeptide after editing (CtoA+PSkill).

(3) Introduce the C to A mutation of (1) and additional silent substitutions promoting favorable DNA repair incorporating the C to A mutation (CtoA+subs).

(4) Introduce a T to C mutation, similar to that needed to correct PKU-associated R408W in human PAH (TtoC).

In this example, a template RNA contained:

(1) a gRNA spacer;

(2) a gRNA scaffold;

(3) a heterologous object sequence; and

(4) a primer binding site (PBS) sequence.

Exemplary template RNAs contained one of the following four spacer sequences:

cPKU4: GGGUCAUAGCGAACUGAGAA (SEQ ID NO: 30481)

cPKU5.1: UAGCGAACUGAGAAGGGCCG (SEQ ID NO: 30482)

cPKU5.2: AGCGAACUGAGAAGGGCCGA (SEQ ID NO: 30483)

cPKU6: ACUUUGCUGCCACAAUCCCU (SEQ ID NO: 30484)

The exemplary gene modifying polypeptide was RNAIVT338 (described in Example 8). mRNA encoding RNAIVT338 and template RNA were transfected into HEK293T cells containing a genomic modification which inserted the ***M fascicularis*** PAH gene. After transfection, HEK293T cells were cultured for at least 4 days and then assayed for rewriting by isolating genomic DNA, conducting PCR using primers flanking the ***M fascicularis*** PAH gene, and then sequencing the amplicons using Amp-Seq.

FIG. 23 shows a graph of percent rewriting for the 4 different mutation types using the template RNAs containing the four spacer sequences under evaluation (where each dot represents that column's spacer combined with a particular of RT and PBS sequence). CtoA, CtoA+PSkill, CtoA+subs, and TtoC mutations were observed when utilizing each of the spacer sequences tested, but with different rewriting % levels. For example: a large number of template RNAs containing spacer cPKU5.2 yielded high rewriting % for CtoA+PSkill mutation and TtoC mutation; a large number of template RNAs containing spacer cPKU6 yielded high rewriting % for CtoA, CtoA+PSkill, and CtoA+subs mutations; a large number of template RNAs containing spacer cPKU5.2 yielded high rewriting % for CtoA+PSkill and CtoA+subs mutations. The

results show that gene modifying systems comprising an exemplary gene modifying polypeptide and template RNAs containing four different exemplary spacer sequences enabled 4 different PKU-relevant genetic modifications to a primate PAH gene.

Example 11: Evaluating template RNA/second strand-targeting gRNA dose response in correction of an F263S mutation in a murine Pah gene in murine model animals

This example describes the use of exemplary gene modifying systems containing a gene modifying polypeptide, either of two template RNAs (each comprising different spacers, lengths and compositions of heterologous object sequences, and PBS sequences), and a second strand-targeting gRNA to evaluate the dose response of template RNA and second strand-targeting gRNA level to rewriting activity (the correction of an F263S mutation (corresponding to a T835C base change) in the murine *Pah* gene). Two different concentrations of template RNA and second strand-targeting gRNA (1.2 milligrams per kilogram body weight (mpk) and 2.4 mpk) were evaluated. In this example, a template RNA contained:

(1) a gRNA spacer;
(2) a gRNA scaffold;
(3) a heterologous object sequence; and
(4) a primer binding site (PBS) sequence.

Exemplary template RNAs tested were template RNAs RNACS1855 and RNACS2303, shown in Table E1. The exemplary second strand-targeting gRNA was ngRNA5 (also referred to herein as RNACS2101), shown in Table E2. The exemplary gene modifying polypeptide used was RNAIVT338 (as described above and corresponding to the amino acid sequence of SEQ ID NO: 30480.

The gene modifying system was formulated in LNP and delivered to mice. Specifically, 1.2 or 2.4 mpk of total RNA equivalent formulated in LNPs, combined at 1:1 (w/w) of template RNA and mRNA or 1:1:1 (w/w/w) when including ngRNA, were dosed intravenously in 8 to 10-week-old, mixed gender ENU2 mice (0.8 mg/kg each of template RNA and mRNA, optionally with an additional 0.8 mg/kg of ngRNA for second strand-targeting experiments; or 0.4 mg/kg each of template RNA and mRNA, optionally with an additional 0.4 mg/kg of ngRNA for second strand-targeting experiments,) in a 10 ml/kg bolus. Mice were administered a first dose at

time 0 (t = 0) and a second dose 24 hours later (t = 24). 7 days post-dosing, animals were sacrificed, and their liver and plasma collected for analyses.

7-day liver samples were analyzed using Amp-Seq to determine % rewriting in target liver cells (**FIG. 24A**). To analyze gene editing activity, primers flanking the target insertion site locus were used to amplify across the locus in the genomic DNA of liver samples. Amplicons were analyzed via short read sequencing using an Illumina MiSeq. Conversion of a C nucleotide to a T nucleotide at position 835 in the PAH gene indicates successful editing. Rewriting was observed from all treated mice except for RNACS2303 without second strand-targeting gRNA. This is consistent with the interpretation that RNACS2303 is less effective at facilitating rewriting at this locus than RNACS1855 in the absence of a second strand-targeting gRNA, and that the presence of a second strand-targeting gRNA increases rewriting activity. As the dose of template RNA and second strand-targeting gRNA increased, so did the % rewriting. This suggests that the amount of template RNA and/or second strand-targeting gRNA can be adjusted to achieve a desired (e.g., sufficient) level of rewriting activity corresponding to a therapeutic outcome. Amplicon sequencing was also used to evaluate the degree to which INDELs were introduced into the liver sample DNA (**FIG. 24B**). % INDEL increased with template RNA and second strand-targeting gRNA dosage, correlating with % rewriting. The results suggest that the amount of template RNA and/or second strand-targeting gRNA can be adjusted to decrease (e.g., minimize) the % INDEL while achieving a desired (e.g., sufficient) level of rewriting activity corresponding to a therapeutic outcome.

7-day plasma samples were also analyzed by LC/MS to determine the level of phenylalanine present. ENU2 mice harbor a mutation (F263S) in the murine PAH gene that inactivates the PAH enzyme, resulting in sharply higher Phe levels in plasma than healthy wildtype mice. The ENU2 mutation is described by The Jackson Laboratory (https://www.jax.org/strain/002232) as a T835C missense mutation in the murine PAH gene, however the mutation is also described in the literature as being a T788C mutation (see, e.g., Harding, C.O. Mol Front J. 2019 Dec;3(2):110-121; or Pecimonova, M. Genes (Basel). 2019 Jun 15;10(6):459). The Examples explicitly contemplate both positions whenever reference is made to either nucleotide mutation herein.

Phenylalanine was extracted from mouse plasma using protein precipitation and then analyzed by a LC-MS/MS system equipped with a Shimadzu Nexera UPLC (LC-40) coupled to

a Sciex API 7500 mass spectrometer. Surrogate analyte (13C2,15N-Phenylalanine) was used for phenylalanine quantitation. Equivalence of ionization for naturally occurring and surrogate compounds was established prior to and after analytical run. Data were collected in the positive ion mode with three MRM transitions, 169.1 to 123.1 (13C2,15N-Phenylalanine), 166.1 to 120.1(Phenylalanine) and 172.1 to 126.0 (13C6-Phenylalanine, internal standard). Extracted samples were injected onto an Acquity UPLC BEH C18 column (1.7µm, 2.1x50 mm) and eluted using a gradient of 0% to 15% of mobile phase B at a flow rate of 0.8 mL/min with a total run time of 3 min per injection. Mobile phase A is 100:2:0.1 H2O:Formic acid (FA): Trifluoroacetic acid (TFA) and mobile phase B is 95:5:2:0.1 ACN:H2O:FA:TFA. Data were processed using Sciex OS software.

The results showed that Phe levels decreased in plasma from all treated mice except for RNACS2303 without second strand-targeting gRNA. This is consistent with the interpretation that RNACS2303 is less effective at facilitating rewriting at this locus than RNACS1855 in the absence of a second strand-targeting gRNA, and that the presence of a second strand-targeting gRNA increases rewriting activity. The results are consistent with correction of the PAH deactivating point mutation using the exemplary gene modifying polypeptide and either of the template RNAs examined (**FIG. 24C**). Treatment with LNP containing RNACS1855 decreased Phe levels more than treatment with LNP containing RNACS2303. Addition of a second strand-targeting gRNA and increasing the dosage of template RNA and second strand-targeting gRNA caused Phe levels to decrease more precipitously in RNACS2303 treated samples. The addition of a second strand-targeting gRNA and increasing the dosage of template RNA and second strand-targeting gRNA caused only small additional Phe levels decreases in RNACS1855 treated samples. These results suggest that a higher dose and/or second strand-targeting gRNA may be necessary to reduce plasma Phe levels to wild-type levels for some template RNAs, but that for highly effective template RNAs a lower dose or omission of second strand-targeting gRNA may be sufficient to reduce plasma Phe to wild-type levels. When considered together (FIGs. 24A-24C), the results show that increasing the template RNA and second strand-targeting gRNA dose increases the % rewriting, as well as % INDEL, and that for highly effective template RNAs a lower dose or omission of second strand-targeting gRNA (despite lower % rewriting) provides a nearly wild-type plasma Phe phenotype.

Example 12: Evaluating Rewriting Activity of Exemplary Human Template RNAs in hPAH Mice

This example describes the use of exemplary gene modifying systems containing a gene modifying polypeptide and template RNAs comprising varied spacers, lengths and compositions of heterologous object sequences, and PBS sequences to quantify the activity of template RNAs for correction of an R408W mutation (corresponding to a C>T base change) in a human PAH (hPAH) gene in vivo in mice modified to carry R408W hPAH.

In this example, a template RNA contained:

(1) a gRNA spacer;

(2) a gRNA scaffold;

(3) a heterologous object sequence; and

(4) a primer binding site (PBS) sequence.

Exemplary template RNAs generated are given in Table E3. Nucleotide modifications are noted as follows: phosphorothioate linkages denoted by an asterisk, 2'-O-methyl groups denoted by an 'm' preceding a nucleotide. The exemplary gene modifying polypeptide is RNAIVT338, comprising the amino acid sequence of SEQ ID NO: 30480.

The gene modifying system comprising RNAIVT338 gene modifying polypeptide and a template RNA described above were formulated in LNP and delivered to mice. Specifically, approximately 1.6 mg/kg of total RNA equivalent formulated in LNPs (4:1 N:P ratio for mRNA, and 3:1 N:P ratio for tgRNA), combined at 1:1 (w/w) of template RNA and mRNA, were dosed intravenously in 8 to 10-week-old, mixed gender hPAH mice (0.8 mg/kg each of template RNA and mRNA) in a 10 ml/kg bolus. Mice were administered a dose at time 0 (t = 0). 7 days post-dosing (as used herein post-dosing refers to time since the first dose), animals were sacrificed, and their liver and plasma are collected for analyses.

7-day plasma samples were analyzed by LC/MS to determine the level of phenylalanine present. hPAH trangenic mice harbor a mutation in the human PAH gene that inactivates the PAH enzyme, resulting in sharply higher Phe levels in plasma than healthy wildtype mice. Successful rewriting of the hPAH transgene would be expected to result in a decrease in Phe levels in plasma.

Phenylalanine was extracted from mouse plasma using protein precipitation and was analyzed by a LC-MS/MS system equipped with a Shimadzu Nexera UPLC (LC-40) coupled to a Sciex API 7500 mass spectrometer. Surrogate analyte (13C2,15N-Phenylalanine) was used for phenylalanine quantitation. Equivalence of ionization for naturally occurring and surrogate compounds was established prior to and after analytical run. Data were collected in the positive ion mode with three MRM transitions, 169.1 to 123.1 (13C2,15N-Phenylalanine), 166.1 to 120.1(Phenylalanine) and 172.1 to 126.0 (13C6-Phenylalanine, internal standard). Extracted samples were injected onto an Acquity UPLC BEH C18 column (1.7µm, 2.1x50 mm) and eluted using a gradient of 0% to 15% of mobile phase B at a flow rate of 0.8 mL/min with a total run time of 3 min per injection. Mobile phase A was 100:2:0.1 H2O:Formic acid (FA): Trifluoroacetic acid (TFA) and mobile phase B wasa 95:5:2:0.1 ACN:H2O:FA:TFA. Data were processed using Sciex OS software.

FIG. 35 shows a graph of Phe levels in plasma from treated mice. The results show that Phe levels decreased in hPAH mice treated with exemplary gene modifying systems. The results further showed that Phe levels decreased most in mice treated with hPKU5 template RNAs, with RNACS4134 showing the steepest decrease in Phe levels. These results show that exemplary

gene modifying systems targeting mutant hPAH in vivo can achieve editing that results in clinically-relevant phenotype changes.

7-day liver samples were analyzed using Amp-Seq to determine % rewriting and % INDELs in target liver cells. To analyze gene editing activity, primers flanking the target insertion site locus were used to amplify across the locus in the genomic DNA of liver samples. Amplicons were analyzed via short read sequencing using an Illumina MiSeq. Conversion of a C nucleotide to a T nucleotide at position 1222 in exon 12 in the human PAH gene indicated successful editing.

FIG. 36A shows a graph of % rewriting level for each of the tested template RNAs. The results showed that hPKU5-spacer-containing template RNAs showed the highest rewriting activity, with RNACS4134 showing the highest rewriting activity of about 4.6%. FIG. 36B shows a graph of %INDEL activity for each of the tested template RNAs. The results showed that all tested template RNAs had very low levels of INDEL generation in hPAH in mouse liver cells, including hPKU5 template RNAs. The results show that exemplary gene modifying systems can be used to specifically correct a clinically relevant mutation in hPAH in vivo in mice.

Example 13: Evaluating Rewriting Activity of Exemplary Human Template RNAs and Second Strand-Targeting gRNAs in Several Cellular Systems

This example describes the use of exemplary gene modifying systems containing a gene modifying polypeptide, template RNAs comprising varied spacers, lengths and compositions of heterologous object sequences, and PBS sequences, and either of two second strand-targeting gRNAs to evaluate the activity of template RNAs and second strand-targeting gRNAs to: 1) produce a R408W mutation into wild-type hPAH in primary human hepatocytes, 2) produce an W408R mutation to correct the R408W mutation in hPAH in CRISPR gene-edited iPSC hepatoblast cells, and 3) produce an W408R mutation to correct the R408W mutation in hPAH transgenic mice (described in Example 12). Combinations of template RNAs and second strand-targeting gRNAs (e.g., sequences, e.g., spacer sequences) that provide high rewriting activity in one or more of (1)-(3) may also provide rewriting activity in therapeutic template RNAs and

second strand-targeting gRNAs designed for correcting pathogenic hPAH mutations in a human subject.

In this example, a template RNA contained:

(1) a gRNA spacer;

(2) a gRNA scaffold;

(3) a heterologous object sequence; and

(4) a primer binding site (PBS) sequence.

Exemplary template RNAs generated and used in iPSC hepatoblast cells and to be used in hPAH transgenic mice are given in Table E5. Exemplary template RNAs generated for use in primary human hepatocytes are given in Table E4. Nucleotide modifications are noted as follows: phosphorothioate linkages denoted by an asterisk, 2'-O-methyl groups denoted by an 'm' preceding a nucleotide. The exemplary gene modifying polypeptide is RNAIVT338, comprising the amino acid sequence of SEQ ID NO: 30480. Exemplary second strand-targeting gRNAs for use with hPKU3, hPKU4, and hPKU5 template RNAs are RNACS1809 and RNACS1810, whereas exemplary second strand-targeting gRNAs for use with hPKU6 template RNAs are RNACS1812, RNACS1834, and RNACS1831, the nucleic acid sequence and chemical modifications of which are given here.

The gene modifying system comprising mRNA encoding the gene modifying polypeptide listed above, a template RNA listed above, and a second strand-targeting gRNA described above were transfected into primary human hepatocytes. The gene modifying polypeptide, template RNA, and second strand-targeting gRNA were delivered by nucleofection in the RNA format. Specifically, 4 µg of gene modifying polypeptide mRNA were combined with 10 µg of chemically synthesized template RNA in 5 µL of water. The transfection mix was added to 100,000 primary hepatocytes in Buffer P3 [Lonza], and cells were nucleofected using program DG-138. After nucleofection, cells were grown at 37˚C, 5% CO_2 for 3 days prior to cell lysis and genomic DNA extraction. To analyze gene editing activity, primers flanking the target insertion site locus were used to amplify across the locus. Amplicons were analyzed via short read sequencing using an Illumina MiSeq. Conversion of C nucleotide to T nucleotide indicates successful editing.

FIG. 25A shows a heatmap of % rewriting for each combination of template RNA and second strand-targeting RNA. The results show that many combinations of exemplary template RNAs and exemplary second strand-targeting gRNAs facilitated installation of the R408W mutation into hPAH gene of primary human hepatocytes.

The gene modifying system comprising mRNA encoding the gene modifying polypeptide listed above, a template RNA listed above, and a second strand-targeting gRNA described above were transfected into hepatoblasts differentiated from CRISPR-edited iPSCs containing the R408W mutation in the human PAH gene. Briefly PAH iPSCs are dissociated into single cells and then replated onto Geltex-coated plates. The iPSCs were then differentiated into definitive endoderm cells by treatment with Activin A, FGF2, and ChIR for 7 days. Definitive endoderm cells are then further patterned into foregut endoderm cells by activation of the BMP4 and FGF2 signaling pathway for an additional 6 days. Lastly, foregut endoderm cells were patterned into hepatoblast cells by treatment with oncostamin M, dexamethasone, hepatocyte growth factors, and ChIR for 12 days. Hepatoblasts were then sub-cultured onto collagen1-coated plates and expanded in media containing FGF19, Dexamethazone, ChIR, and SB431542 prior to transfection. The gene modifying polypeptide, template RNA, and second strand-targeting gRNA were delivered by nucleofection in the RNA format. Specifically, 4 µg of gene modifying polypeptide mRNA were combined with 10 µg of chemically synthesized template RNA, with or

without 10 µg of second strand-targeting gRNA, in 5 µL of water. The transfection mix was added to 100,000 iPSCs in Buffer P3 [Lonza], and cells were nucleofected using program DG-138. After nucleofection, cells were grown at 37˚C, 5% CO_2 for 3 days prior to cell lysis and genomic DNA extraction. To analyze gene editing activity, primers flanking the target insertion site locus were used to amplify across the locus. Amplicons were analyzed via short read sequencing using an Illumina MiSeq. Conversion of T>C indicates successful editing.

FIG. 25B shows a heatmap of % rewriting for each combination of template RNA and second strand-targeting RNA. The results show that many combinations of exemplary template RNAs and exemplary second strand-targeting gRNAs facilitated a corrective W408R mutation in the mutant hPAH gene of iPSC hepatoblasts. In particular, template RNAs RNACS1747, RNACS3877, RNACS4135, RNACS4134, RNACS2300, RNACS2299, RNACS4142, RNACS4173, RNACS4045, RNACS4048, and RNACS1763 showed the highest rewriting activity in this experiment.

The gene modifying system comprising mRNA encoding the gene modifying polypeptide listed above, a template RNA listed above, and a second strand-targeting gRNA described above were nucleofected in primary mouse hepatocytes from transgenic animals harboring the humanized region of exon 12 of the human PAH gene and contain the R408W PAH mutation. The gene modifying polypeptide, template RNA, and second strand-targeting gRNA were delivered by nucleofection in the RNA format. Specifically, 4 µg of gene modifying polypeptide mRNA were combined with 10 µg of chemically synthesized template RNA in 5 µL of water. The transfection mix was added to 100,000 primary hepatocytes in Buffer P3 [Lonza], and cells were nucleofected using program DG-138. After nucleofection, cells were grown at 37˚C, 5% CO_2 for 3 days prior to cell lysis and genomic DNA extraction. To analyze gene editing activity, primers flanking the target insertion site locus were used to amplify across the locus. Amplicons were analyzed via short read sequencing using an Illumina MiSeq. Conversion of C nucleotide to T nucleotide indicates successful editing.

FIG. 25C shows a heatmap of % rewriting for each combination of template RNA and second strand-targeting RNA. The results show that many combinations of exemplary template RNAs and exemplary second strand-targeting gRNAs facilitated a corrective W408R mutation in the mutant hPAH gene of primary mouse hepatocytes. In particular, template RNAs RNACS4134 and RNACS1792 showed the highest rewriting activity in this experiment. In particular, template RNAs RNACS4134 and RNACS1792 showed high rewriting activity in combination with second strand-targeting gRNA RNACS1812 (about 17% and about 14% editing, respectively).

The gene modifying system comprising the gene modifying polypeptide listed above, a template RNA listed above, and a second strand-targeting gRNA listed above is formulated in LNP and delivered to mice. Specifically, approximately 2.4 mg/kg of total RNA equivalent formulated in LNPs (4:1 N:P ratio for mRNA, and 3:1 N:P ratio for tgRNA/gRNA), combined at 1:1:1 (w/w) of template RNA:mRNA:gRNA, are dosed intravenously in 8 to 10-week-old, mixed gender hPAH mice (0.8 mg/kg each of template RNA, mRNA, and gRNA) in a 10 ml/kg bolus. Mice are administered a dose at time 0 (t = 0). 7 days post-dosing (as used herein post-dosing refers to time since the first dose), animals are sacrificed, and their liver and plasma are collected for analyses.

7-day plasma samples are analyzed by LC/MS to determine the level of phenylalanine present. Using CRISPR, hPAH transgenic mice were generated with a humanized region of exon 12 of the human PAH gene and contain the R408W PAH mutation that inactivates the PAH enzyme, resulting in sharply higher Phe levels in plasma than healthy wildtype mice. Successful rewriting of the hPAH transgene is expected to result in a decrease in Phe levels in plasma.]]

Phenylalanine is extracted from mouse plasma using protein precipitation and is analyzed by a LC-MS/MS system equipped with a Shimadzu Nexera UPLC (LC-40) coupled to a Sciex API 7500 mass spectrometer. Surrogate analyte (13C2,15N-Phenylalanine) is used for phenylalanine quantitation. Equivalence of ionization for naturally occurring and surrogate compounds is established prior to and after analytical run. Data are collected in the positive ion mode with three MRM transitions, 169.1 to 123.1 (13C2,15N-Phenylalanine), 166.1 to 120.1(Phenylalanine) and 172.1 to 126.0 (13C6-Phenylalanine, internal standard). Extracted samples are injected onto an Acquity UPLC BEH C18 column (1.7µm, 2.1x50 mm) and eluted

using a gradient of 0% to 15% of mobile phase B at a flow rate of 0.8 mL/min with a total run time of 3 min per injection. Mobile phase A is 100:2:0.1 H2O:Formic acid (FA): Trifluoroacetic acid (TFA) and mobile phase B is 95:5:2:0.1 ACN:H2O:FA:TFA. Data are processed using Sciex OS software.

The results will show that Phe levels decreased in plasma from mice with exemplary gene modifying systems targeting hPAH.

7-day liver samples are analyzed using Amp-Seq to determine % rewriting in target liver cells. To analyze gene editing activity, primers flanking the target insertion site locus are used to amplify across the locus in the genomic DNA of liver samples. Amplicons are analyzed via short read sequencing using an Illumina MiSeq. Conversion of a T nucleotide to a C nucleotide at position 1222 in the PAH gene indicates successful editing. The results will show that rewriting is observed in mice treated with exemplary gene modifying systems targeting hPAH.

Example 14: Evaluating the Rewriting Activity Over Time and Short-Term Safety of Exemplary Murine Template RNAs and Second Strand-Targeting gRNAs in an ENU2 Mouse Model

This example describes the use of exemplary gene modifying systems containing a gene modifying polypeptide, an exemplary template RNA, and exemplary second strand-targeting gRNA to evaluate the stability of rewriting over time and the short term safety of gene modifying systems used to correct the F263S mutation in ENU2 mice.

In this example, a template RNA contained:

(1) a gRNA spacer;

(2) a gRNA scaffold;

(3) a heterologous object sequence; and

(4) a primer binding site (PBS) sequence.

The exemplary template RNA tested was template RNA RNACS1855 shown in Table E1. The exemplary second strand-targeting gRNA was ngRNA5 (also referred to herein as RNACS2101), shown in Table E2. The exemplary gene modifying polypeptide used was RNAIVT338 (as described above and corresponding to the amino acid sequence of SEQ ID NO: 30480).

The gene modifying system was formulated in LNP and delivered to mice. [[Specifically, 2.4 mpk of total RNA equivalent formulated in LNPs, combined at 1:1 (w/w) of template RNA and mRNA, were dosed intravenously in 8 to 10-week-old, mixed gender ENU2 mice (0.8 mg/kg each of template RNA and mRNA with an additional 0.8 mg/kg of ngRNA in a 10 ml/kg bolus. Mice were administered a dose at time 0 (t = 0). 7 days and 28 days post-dosing, animals were sacrificed, and their liver, brain, plasma collected for analyses.

7-day and 28-day liver samples were analyzed using Amp-Seq to determine % rewriting in target liver cells (**FIG. 26A**). To analyze gene editing activity, primers flanking the target insertion site locus were used to amplify across the locus in the genomic DNA of liver samples. Amplicons were analyzed via short read sequencing using an Illumina MiSeq. Conversion of a C nucleotide to a T nucleotide at position 835 in the PAH gene indicated successful editing. Rewriting was observed from all treated mice at the 7d and 28d timepoints, and the % rewriting at the 7d and 28d timepoints were very similar. Amplicon sequencing was also used to evaluate the degree to which INDELs were introduced into the liver sample DNA (**FIG. 26B**). As seen in other data described herein, the % INDEL was significantly lower than the % rewriting, and the % INDEL at the 7d and 28d timepoints were very similar.

7-day and 28-day plasma and brain samples were also analyzed by LC/MS to determine the level of phenylalanine present. ENU2 mice harbor a mutation in the murine PAH gene that inactivates the PAH enzyme, resulting in sharply higher Phe levels in plasma and brain than healthy wildtype mice.

Phenylalanine was extracted from mouse plasma and brain using protein precipitation and then analyzed by a LC-MS/MS system equipped with a Shimadzu Nexera UPLC (LC-40) coupled to a Sciex API 7500 mass spectrometer. Surrogate analyte (13C2,15N-Phenylalanine) was used for phenylalanine quantitation. Equivalence of ionization for naturally occurring and surrogate compounds was established prior to and after analytical run. Data were collected in the positive ion mode with three MRM transitions, 169.1 to 123.1 (13C2,15N-Phenylalanine), 166.1 to 120.1(Phenylalanine) and 172.1 to 126.0 (13C6-Phenylalanine, internal standard). Extracted samples were injected onto an Acquity UPLC BEH C18 column (1.7µm, 2.1x50 mm) and eluted using a gradient of 0% to 15% of mobile phase B at a flow rate of 0.8 mL/min with a total run time of 3 min per injection. Mobile phase A is 100:2:0.1 H2O:Formic acid (FA): Trifluoroacetic

acid (TFA) and mobile phase B is 95:5:2:0.1 ACN:H2O:FA:TFA. Data were processed using Sciex OS software.

The results showed that Phe levels decreased in plasma from all treated mice, consistent with correction of the PAH deactivating point mutation using the gene modifying polypeptide and template RNAs examined (**FIG. 27**). The plasma Phe levels were consistently low at the 7d and 28d timepoints, showing that treated mice achieved stable Phe levels comparable to strain-matched wildtype mice at least out to 28d. When considered together (FIGs. 26A-27), the results show that the exemplary gene modifying systems can be used to specifically rewrite the mPAH gene of ENU2 mice, resulting in stable genetic modification and stable therapeutic phenotypic change.

The results showed that Phe levels decreased in brain from all treated mice, consistent with correction of the PAH deactivating point mutation using the gene modifying polypeptide and template RNAs examined (**FIG. 28**). The brain Phe levels were consistently low at the 7d and 28d timepoints, showing that treated mice achieved stable Phe levels comparable to strain-matched wildtype mice at least out to 28d. When considered together (FIGs. 26A-26B and 28), the results show that the exemplary gene modifying systems can be used to specifically rewrite the mPAH gene of ENU2 mice, resulting in stable genetic modification and stable therapeutic phenotypic change.

FIG. 29 shows a graph plotting correlation of plasma and brain Phe levels from samples used to generate FIGs. 27 and 28. The results show that plasma Phe level and brain Phe levels strongly correlate, with samples derived from saline treated ENU2 mice having higher Phe levels in plasma and in brain and samples derived from ENU2 mice treated with exemplary gene modifying systems as described herein having much lower Phe levels in plasma and in brain, similar to samples from saline treated wildtype mice.

At 90 days post dosing, animals are sacrificed, and their liver, brain, and plasma collected for analyses. The above analyses of % rewriting, % INDEL, and plasma Phe level are repeated with 90d liver, brain, and plasma samples. The results will show comparable rewriting and INDEL

levels to 7d and 28d samples from treated mice, and comparable Phe plasma and brain levels to 7d and 28d samples from treated mice.

Example 15: Evaluating Rewriting Activity of Exemplary Template RNAs and Second Strand-Targeting gRNAs in Cynomolgus macaque hepatocytes

This example describes the use of exemplary gene modifying systems containing a gene modifying polypeptide, template RNAs comprising varied spacers, lengths and compositions of heterologous object sequences, and PBS sequences, and either of two second strand-targeting gRNAs to evaluate the activity of template RNAs and second strand-targeting gRNAs to produce a R408 silent mutation (C to A) or P407 silent mutation (T to C) mutation into wild-type PAH in primary cyno hepatocytes. Sequences (e.g., spacer sequences) of template RNAs or combinations of sequences of template RNAs and second strand-targeting gRNAs that provide high rewriting activity in a comparable model system may also provide rewriting activity in therapeutic template RNAs and second strand-targeting gRNAs designed for correcting pathogenic hPAH mutations in a human subject.

In this example, a template RNA contained:

(1) a gRNA spacer;
(2) a gRNA scaffold;
(3) a heterologous object sequence; and
(4) a primer binding site (PBS) sequence.

Exemplary template RNAs generated and used are given in Table EX. Nucleotide modifications are noted as follows: phosphorothioate linkages denoted by an asterisk, 2'-O-methyl groups denoted by an 'm' preceding a nucleotide. The exemplary gene modifying polypeptide is RNAIVT338, comprising the amino acid sequence of SEQ ID NO: 30480. Exemplary second strand-targeting gRNAs for use with cPKU4, cPKU5.1, and cPKU5.2 template RNAs are RNACS1809 and RNACS1810, whereas exemplary second strand-targeting gRNAs for use with cPKU6 template RNAs are RNACS1906, RNACS1812, and RNACS1813, the nucleic acid sequence and chemical modifications of which are given here.

The gene modifying system comprising mRNA encoding the gene modifying polypeptide listed above, a template RNA listed above, and a second strand-targeting gRNA described above were transfected into primary cyno hepatocytes. The gene modifying polypeptide, template RNA, and second strand-targeting gRNA were delivered by nucleofection in the RNA format. Specifically, 4 µg of gene modifying polypeptide mRNA were combined with 4 µg of chemically synthesized template RNA and 4 ug of nicking gRNA in 5 µL of water. The transfection mix was added to 100,000 primary hepatocytes in Buffer P3 [Lonza], and cells were nucleofected using program DG-138. After nucleofection, cells were grown at 37˚C, 5% CO_2 for 3 days prior to cell lysis and genomic DNA extraction. To analyze gene editing activity, primers flanking the target insertion site locus were used to amplify across the locus. Amplicons were analyzed via short read sequencing using an Illumina MiSeq. Conversion of T to C or C to A nucleotide indicated successful editing.

FIGS. 30A-30H show heatmaps of % rewriting for each combination of template RNA and second strand-targeting RNA, with FIGs. 30A-30D showing C to A rewriting and FIGs. 30E-30H showing T to C rewriting and grouped by the spacer of the template RNA. The results show that many combinations of exemplary template RNAs and exemplary second strand-targeting gRNAs facilitated installation of the silent mutations at R408 or P407 positions into cPAH gene of primary cyno hepatocytes. The results showed that for C to A editing, cPKU6 template RNAs showed the highest % rewriting compared to other spacers. For this edit, the second strand-targeting gRNA RNACS1906 showed the highest % rewriting combined with cPKU6 template RNAs (e.g., RNACS2827 template RNA combined with RNACS1906 showed 43% rewriting). The results showed that for T to C editing, cPKU5.2 template RNAs showed the highest % rewriting compared to other spacers, followed by cPKU6 template RNAs. For this edit, the second strand-targeting gRNA RNACS1810 showed the highest % rewriting combined with cPKU5.2 template RNAs (e.g., RNACS3349 template RNA combined with RNACS1810 showed 57% rewriting), whereas the second strand-targeting gRNA RNACS1906 showed the highest % rewriting combined with cPKU6 template RNAs.

Example 16: Evaluating Impact of Different Silent Substitutions on Rewriting Activity in human iPSC-derived hepatoblasts

This example describes the use of exemplary gene modifying systems containing a gene modifying polypeptide and template RNAs comprising four different spacers (hPKU3, hPKU4, hPKU5, and hPKU6), five lengths of heterologous object sequences, and three lengths of PBS sequences, wherein the template RNAs comprised one of five different silent substitutions. The example describes evaluation of the activity of template RNAs containing said silent substitutions to produce an W408R mutation to correct the R408W mutation in hPAH in CRISPR gene-edited iPSC-derived hepatoblast cells.

In this example, a template RNA contained:

(1) a gRNA spacer;

(2) a gRNA scaffold;

(3) a heterologous object sequence; and

(4) a primer binding site (PBS) sequence.

Exemplary template RNAs generated and used are given in Table E6. Nucleotide modifications are noted as follows: phosphorothioate linkages denoted by an asterisk, 2'-O-methyl groups denoted by an 'm' preceding a nucleotide. The exemplary gene modifying polypeptide is RNAIVT338, comprising the amino acid sequence of SEQ ID NO: 30480.

The gene modifying system comprising mRNA encoding the gene modifying polypeptide listed above and a template RNA listed above were transfected into human hepatoblasts differentiated from CRISPR-edited iPSCs containing the R408W mutation in the human PAH gene. Briefly PAH iPSCs are dissociated into single cells and then replated onto Geltex-coated plates. The iPSCs were then differentiated into definitive endoderm cells by treatment with Activin A, FGF2, and ChIR for 7 days. Definitive endoderm cells are then further patterned into foregut endoderm cells by activation of the BMP4 and FGF2 signaling pathway for an additional 6 days. Lastly, foregut endoderm cells were patterned into hepatoblast cells by treatment with oncostamin M, dexamethasone, hepatocyte growth factors, and ChIR for 12 days. Hepatoblasts were then sub-cultured onto collagen1-coated plates and expanded in media containing FGF19, Dexamethazone, ChIR, and SB431542 prior to transfection. The gene modifying polypeptide and template RNA were delivered by nucleofection in the RNA format. Specifically, 4 µg of gene modifying polypeptide mRNA were combined with 10 µg of chemically synthesized template RNA, in 5 µL of water. The transfection mix was added to 100,000 iPSCs in Buffer P3 [Lonza], and cells were nucleofected using program DG-138. After nucleofection, cells were grown at 37˚C, 5% CO_2 for 3 days prior to cell lysis and genomic DNA extraction. To analyze gene editing activity, primers flanking the target insertion site locus were used to amplify across the locus. Amplicons were analyzed via short read sequencing using an Illumina MiSeq. Conversion of T>C indicates successful editing.

As shown by FIG. 31A, treating hepatoblasts with gene modifying systems comprising exemplary hPKU3 template RNAs comprising a variety of silent substitutions (FIG. 31B) resulted in editing at the target locus. The results show that silent substitution 4 (sub4) resulted in comparable rewriting % as the template RNA without silent substitutions, whereas other silent substitutions resulted in lower rewriting %.

As shown by FIG. 32A, treating hepatoblasts with gene modifying systems comprising exemplary hPKU4 template RNAs comprising a variety of silent substitutions (FIG. 32B) resulted in editing at the target locus. The results show that silent substitution 4 (sub4) resulted in comparable or higher rewriting % as the template RNA without silent substitutions, whereas other silent substitutions resulted in lower rewriting %.

As shown by FIG. 33A, treating hepatoblasts with gene modifying systems comprising exemplary hPKU5 template RNAs comprising a variety of silent substitutions (FIG. 33B)

resulted in editing at the target locus. The results show that silent substitution 4 (sub4) resulted in comparable or higher rewriting % as the template RNA without silent substitutions, whereas other silent substitutions resulted in lower rewriting %.

As shown by FIG. 34A, treating hepatoblasts with gene modifying systems comprising exemplary hPKU6 template RNAs comprising a variety of silent substitutions (FIG. 34B) resulted in editing at the target locus. The results show that silent substitutions 5, 6, and 7 (sub5, sub6, and sub7, respectively) resulted in much higher rewriting % as the template RNA without silent substitutions, which had a very low rewriting %. These results demonstrate that silent substitutions can rescue the low rewriting activity of exemplary hPKU6 template RNAs.

Taken together, these results demonstrate that silent substitutions can increase the rewriting activity of exemplary template RNAs that target a therapeutically relevant human locus, and in some cases rescue otherwise low rewriting activity.

It should be understood that for all numerical bounds describing some parameter in this application, such as “about,” “at least,” “less than,” and “more than,” the description also necessarily encompasses any range bounded by the recited values. Accordingly, for example, the description “at least 1, 2, 3, 4, or 5” also describes, inter alia, the ranges 1-2, 1-3, 1-4, 1-5, 2-3, 2-4, 2-5, 3-4, 3-5, and 4-5, et cetera.

For all patents, applications, or other reference cited herein, such as non-patent literature and reference sequence information, it should be understood that they are incorporated by reference in their entirety for all purposes as well as for the proposition that is recited. Where any conflict exists between a document incorporated by reference and the present application, this application will control. All information associated with reference gene sequences disclosed in this application, such as GeneIDs or accession numbers (typically referencing NCBI accession numbers), including, for example, genomic loci, genomic sequences, functional annotations, allelic variants, and reference mRNA (including, e.g., exon boundaries or response elements) and protein sequences (such as conserved domain structures), as well as chemical references (e.g., PubChem compound, PubChem substance, or PubChem Bioassay entries, including the annotations therein, such as structures and assays, et cetera), are hereby incorporated by reference in their entirety.

Headings used in this application are for convenience only and do not affect the interpretation of this application.
