

METHOD OF INTRA PREDICTING A BLOCK OF A PICTURE

TECHNICAL FIELD

- 5 The present disclosure relates to the technical field of image and/or video coding and decoding, and in particular to a method and apparatus for intra prediction.

BACKGROUND

Digital video has been widely used since the introduction of DVD-discs. Before transmission the video is encoded and is transmitted using a transmission medium. The viewer receives the
10 video and uses a viewing device to decode and display the video. Over the years the quality of video has improved, for example, because of higher resolutions, color depths and frame rates. This has lead into larger data streams that are nowadays commonly transported over internet and mobile communication networks.

Higher resolution videos, however, typically require more bandwidth as they have more
15 information. In order to reduce bandwidth requirements video coding standards involving compression of the video have been introduced. When the video is encoded the bandwidth requirements (or corresponding memory requirements in case of storage) are reduced. Often this reduction comes at the cost of quality. Thus, the video coding standards try to find a balance between bandwidth requirements and quality.

20 The High Efficiency Video Coding (HEVC) is an example of a video coding standard that is commonly known to persons skilled in the art. In HEVC, to split a coding unit (CU) into prediction units (PU) or transform units (TUs). The Versatile Video Coding (VVC) next generation standard is the most recent joint video project of the ITU-T Video Coding Experts Group (VCEG) and the ISO/IEC Moving Picture Experts Group (MPEG) standardization
25 organizations, working together in a partnership known as the Joint Video Exploration Team (JVET). VVC is also referred to as ITU-T H.266/Next Generation Video Coding (NGVC) standard. In VVC, the concepts of multiple partition types shall be removed, i.e. the separation of the CU, PU and TU concepts except as needed for CUs that have a size too large for the maximum transform length, and supports more flexibility for CU partition shapes.

Processing of these coding units (CUs) (also referred to as blocks) depend on their size, spatial position and a coding mode specified by an encoder. Coding modes can be classified into two groups according to the type of prediction: intra-prediction and inter-prediction modes. Intra prediction modes use samples of the same picture (also referred to as frame or image) to generate reference samples to calculate the prediction values for the samples of the block being reconstructed. Intra prediction is also referred to as spatial prediction. Inter-prediction modes are designed for temporal prediction and uses reference samples of previous or next pictures to predict samples of the block of the current picture.

ITU-T VCEG (Q6/16) and ISO/IEC MPEG (JTC 1/SC 29/WG 11) are studying the potential need for standardization of future video coding technology with a compression capability that significantly exceeds that of the current HEVC standard (including its current extensions and near-term extensions for screen content coding and high-dynamic-range coding). The groups are working together on this exploration activity in a joint collaboration effort known as the Joint Video Exploration Team (JVET) to evaluate compression technology designs proposed by their experts in this area.

The VTM (Versatile Test Model) version 3.0 uses 93 intra prediction modes, and several intra smoothing tools, including four-tap subpixel intra interpolation filtering and position-dependent prediction combination (PDPC). PDPC is proposed as a unified mechanism of modification of predicted samples that are a results of intra prediction using DC, PLANAR or angular intra prediction modes.

SUMMARY

Embodiments of the present application provide apparatuses and methods for improved intra prediction of a current block of a picture. The invention is defined by the independent claims. The dependent claims describe advantageous embodiments. Further implementation forms are apparent from the description and the figures.

According to a first aspect, a method of intra predicting a block of a picture is provided, the method comprising for a sample of the block: obtaining a predicted sample value from one or more reference sample values by intra-prediction using a DC intra-prediction mode; multiplying the predicted sample value by a sample weighting factor, resulting in a weighted predicted sample value; adding an additional value to the weighted predicted sample value, resulting in a non-normalized predicted sample value; and normalizing the non-normalized

predicted sample value by an arithmetic right shift of an integer representation of the non-normalized predicted sample value, wherein the sample weighting factor is $((2 \ll p) - wL - wT)$, wherein p is a parameter of the sample weighting factor, wL is a horizontal weighting factor, and wT is a vertical weighting factor.

- 5 According to a second aspect, a method of intra-predicting a first block and a second block of a picture is provided, the method comprising for a sample of the first block and for a sample of the second block: obtaining (S100) a predicted sample value from one or more reference sample values by intra-prediction using an intra-prediction mode; multiplying the predicted sample value by a sample weighting factor, resulting in a weighted predicted sample value; adding an additional value
10 to the weighted predicted sample value, resulting in a non-normalized predicted sample value; and normalizing the non-normalized predicted sample value by an arithmetic right shift of an integer representation of the non-normalized predicted sample value, wherein the sample weighting factor is $((2 \ll p) - wL - wT)$, p is a parameter of the sample weighting factor, wL is a horizontal weighting factor, and wT is a vertical weighting factor, wherein the intra-prediction mode used for
15 obtaining the predicted sample values for the first block is a DC intra-prediction mode, and the intra-prediction mode used for obtaining the predicted sample values for the second block is a PLANAR intra-prediction mode.

For example, the parameter of the sample weighting factor is a precision of the sample weighting factor.

- 20 In some embodiment, the normalized predicted sample value may be the final result of the prediction process.

The method according to the first or second aspect may allow for improved intra-prediction of a current block, wherein the occurrence of erroneous predicted sample values may be prevented in a case of DC intra prediction of a current sample.

- 25 In an embodiment, a PLANAR intra prediction mechanism is used to calculate the additional value.

- This may allow for a reduced degree of complexity by simplifying a procedure for intra-prediction as an already implemented planar intra prediction mechanism may be reused for calculation of the additional values, which are used for determination of the non-normalized
30 predicted sample value.

In an embodiment, the sample weighting factor is $(64 - wL - wT)$.

In an embodiment, the additional value is a sum of one or more summands, including a summand depending on one or more of the reference samples.

For example, the one or more summands may include a rounding offset.

- 5 Adding a rounding offset may allow for the result of the arithmetic right shift of the integer representation of the non-normalized predicted sample being properly rounded.

In an embodiment, the summand depending on one or more reference samples is $wL \times R_{-1,y} + wT \times R_{x,-1}$, and $R_{x,-1}$ and $R_{-1,y}$ represent values of the nearest reference samples located above and to the left of the predicted sample

- 10 In an embodiment, the picture is part of a video sequence.

In an embodiment, the horizontal weighting factor wL and the vertical weighting factor wT are a power of two.

This allows a calculation of a multiplication with said weighting factors to be implemented using a shift operation of an integer representation of the factor the weighting factor is to be multiplied with.

15

In an embodiment, the horizontal weighting factor is $wL = (2 \ll (p - 1)) \gg ((x \ll 1) \gg nScale)$, wherein x is a horizontal coordinate of the sample, the vertical weighting factor is $wT = (2 \ll (p - 1)) \gg ((y \ll 1) \gg nScale)$, wherein y is a vertical coordinate of the sample, and $nScale$ is a scale parameter.

- 20 In an embodiment, the scale parameter $nScale$ is derived from a size of the block.

Deriving the parameter $nScale$ from the size of the block may allow for calculating the horizontal and vertical weights in a suitable manner, thereby improving the prediction accuracy.

- In an embodiment, the scale parameter $nScale$ is determined as $((\text{Log2}(nTbW) + \text{Log2}(nTbH) - 2) \gg 2)$ where $nTbW$ is a width of the block and $nTbH$ is a height of the block.

25

In an embodiment, a normalized predicted sample value is computed from the predicted sample value, including calculating

$$(wL \times R_{-1,y} + wT \times R_{x,-1} + (64 - wL - wT) \times P(x,y) + 32) \gg 6$$

where

5 $P(x,y)$ is the predicted sample value,

$R_{x,-1}$, $R_{-1,y}$ represent the values of the nearest reference samples located above and to the left of the predicted sample,

wL is a horizontal weighting factor, and

wT is a vertical weighting factor.

10 In the embodiment, the added rounding offset is 32.

This may allow a properly rounded calculation result of the right shift operation $\gg 6$.

In an embodiment, the normalizing of the non-normalized predicted sample value results in a normalized predicted sample value.

In an embodiment, the plurality of samples of the block comprises every sample of the block.

15 Further provided is a method of encoding or decoding a picture, comprising obtaining normalized predicted sample values by performing the steps of any one of above methods; and adding residual values to the normalized predicted sample values resulting in reconstructed sample values.

20 According to a third aspect, a device for encoding or decoding a picture is provided, the device comprising processing circuitry configured to perform any one of the above methods.

In an embodiment, the processing circuitry comprises one or more processors and a non-transitory computer-readable medium connected to the one or more processors, wherein the non-transitory computer-readable medium carries a program code which, when executed by the one or more processors, causes the device to perform the method.

According to a fourth aspect, a non-transitory computer-readable medium is provided, the non-transitory computer-readable medium carrying a program code which, when executed by a computer device, causes the computer device to perform any one of the above methods.

5 According to a fifth aspect, a computer program is provided, the computer program comprising program code for performing any one of the above methods.

According to an aspect, an encoder device is provided, the encoder device being configured to perform intra predicting a block of a picture, comprising: an obtainer configured to obtain a predicted sample value from one or more reference sample values by intra-prediction using a DC intra-prediction mode; a multiplier configured to multiply the predicted sample value by a sample weighting factor, resulting in a weighted predicted sample value; an adder configured to add an additional value to the weighted predicted sample value, resulting in a non-normalized predicted sample value; and a normalizer configured to normalize the non-normalized predicted sample value by an arithmetic right shift of an integer representation of the non-normalized predicted sample value, wherein the sample weighting factor is
 10 $((2 \ll p) - wL - wT)$, wherein p is a parameter of the sample weighting factor, wL is a horizontal weighting factor, and wT is a vertical weighting factor.
 15

According to an aspect, an encoder device is provided, the encoder device being configured to perform intra predicting a first block and a second block of a picture, comprising: an obtainer configured to obtain a predicted sample value from one or more reference sample values by intra-prediction using a intra-prediction mode; a multiplier configured to multiply the predicted sample value by a sample weighting factor, resulting in a weighted predicted sample value; an adder configured to add an additional value to the weighted predicted sample value, resulting in a non-normalized predicted sample value; and a normalizer configured to normalize the non-normalized predicted sample value by an arithmetic right shift of an integer representation of the non-normalized predicted sample value, wherein the sample weighting factor is
 20 $((2 \ll p) - wL - wT)$, wherein p is a parameter of the sample weighting factor, wL is a horizontal weighting factor, and wT is a vertical weighting factor. The intra-prediction mode used for obtaining the predicted sample value for a sample of the first block is a DC intra-prediction mode, and the intra prediction mode used for obtaining the predicted sample value for a sample of
 25 the second block is a planar intra prediction mode.
 30

According to an aspect, a decoder device is provided, the decoder device being configured to perform intra predicting a block of a picture, comprising: an obtainer configured to obtain, a predicted sample value from one or more reference sample values by intra-prediction using a DC intra-prediction mode; a multiplier configured to multiply the predicted sample value by a sample weighting factor, resulting in a weighted predicted sample value; an adder configured to add an additional value to the weighted predicted sample value, resulting in a non-normalized predicted sample value; and a normalizer configured to normalize the non-normalized predicted sample value by an arithmetic right shift of an integer representation of the non-normalized predicted sample value, wherein the sample weighting factor is $((2 \ll p) - wL - wT)$, wherein p is a parameter of the sample weighting factor, wL is a horizontal weighting factor, and wT is a vertical weighting factor.

According to an aspect, a decoder device is provided, the decoder device being configured to perform intra predicting a first block and a second block of a picture, comprising: an obtainer configured to obtain, a predicted sample value from one or more reference sample values by intra-prediction using a intra-prediction mode; a multiplier configured to multiply the predicted sample value by a sample weighting factor, resulting in a weighted predicted sample value; an adder configured to add an additional value to the weighted predicted sample value, resulting in a non-normalized predicted sample value; and a normalizer configured to normalize the non-normalized predicted sample value by an arithmetic right shift of an integer representation of the non-normalized predicted sample value, wherein the sample weighting factor is $((2 \ll p) - wL - wT)$, wherein p is a parameter of the sample weighting factor, wL is a horizontal weighting factor, and wT is a vertical weighting factor. The intra-prediction mode used for obtaining the predicted sample value for a sample of the first block is a DC intra-prediction mode, and the intra prediction mode used for obtaining the predicted sample value for a sample of the second block is a planar intra prediction mode.

According to an aspect, a predictor device for intra predicting a block of a picture comprises: an obtainer configured to obtain, for a sample of the block, a predicted sample value from one or more reference sample values by intra-prediction using a DC intra-prediction mode; a multiplier configured to multiply the predicted sample value by a sample weighting factor, resulting in a weighted predicted sample value; an adder configured to add an additional value to the weighted predicted sample value, resulting in a non-normalized predicted sample value; and a normalizer configured to normalize the non-normalized predicted sample value by an

arithmetic right shift of an integer representation of the non-normalized predicted sample value, wherein the sample weighting factor is $((2 \ll p) - wL - wT)$, wherein p is a parameter of the sample weighting factor, wL is a horizontal weighting factor, and wT is a vertical weighting factor.

- 5 According to an aspect, a predictor device for intra predicting a first block and a second block of a picture comprises: an obtainer configured to obtain, for a sample of the first block or the second block, a predicted sample value from one or more reference sample values by intra-prediction using an intra-prediction mode; a multiplier configured to multiply the predicted sample value by a sample weighting factor, resulting in a weighted predicted sample value; an
 10 adder configured to add an additional value to the weighted predicted sample value, resulting in a non-normalized predicted sample value; and a normalizer configured to normalize the non-normalized predicted sample value by an arithmetic right shift of an integer representation of the non-normalized predicted sample value, wherein the sample weighting factor is $((2 \ll p) - wL - wT)$, p is a parameter of the sample weighting factor, wL is a horizontal
 15 weighting factor, and wT is a vertical weighting factor. The intra-prediction mode used for obtaining the predicted sample value for the first block is a DC intra-prediction mode, and the intra prediction mode used for obtaining the predicted sample value for the second block is a planar intra prediction mode.

According to an aspect, a method of intra predicting a block of a picture comprises for a sample
 20 (x,y) of the block:

obtaining a predicted sample value $P(x,y)$ from one or more reference sample values by intra-prediction using a DC intra-prediction mode; and

generating a resultant predicted sample value $P'(x,y)$ based on the predicted sample value $P(x,y)$ and based on reference sample values $R(x,-1)$ and $R(-1,y)$, wherein

25
$$P'(x,y) = (wL \times R(-1,y) + wT \times R(x,-1) + (64 - wL - wT) \times P(x,y) + 32) \gg 6$$

wherein the reference sample value $R(x,-1)$ is a value of a sample (x,-1) located above the block, the reference sample value $R(-1,y)$ is a value of a sample (-1,y) located to the left of the block, wL is a horizontal weighting factor, and wT is a vertical weighting factor.

Details of one or more embodiments are set forth in the accompanying drawings and in the description below. Other features, objects, and advantages will be apparent from the description, drawings, and claims.

BRIEF DESCRIPTION OF THE DRAWINGS

5 In the following embodiments of the disclosure are described in more detail with reference to the attached figures and drawings, in which:

FIG. 1A is a block diagram showing an example of a video coding system configured to implement embodiments of the disclosure;

10 **FIG. 1B** is a block diagram showing another example of a video coding system configured to implement embodiments of the disclosure;

FIG. 2 is a block diagram showing an example of a video encoder configured to implement embodiments of the disclosure;

FIG. 3 is a block diagram showing an example structure of a video decoder configured to implement embodiments of the disclosure;

15 **FIG. 4** is a block diagram illustrating an example of an encoding apparatus or a decoding apparatus;

FIG. 5 is a block diagram illustrating another example of an encoding apparatus or a decoding apparatus;

20 **FIG. 6** illustrates an example of Angular intra prediction directions and modes and the associated value of p_{ang} for vertical prediction directions;

FIG. 7 illustrates an example of Transformation of p_{ref} to $p_{1,ref}$ for a 4×4 block;

FIG. 8 illustrates an example of Construction of $p_{1,ref}$ for horizontal angular prediction;

FIG. 9 illustrates an example of Construction of $p_{1,ref}$ for vertical angular prediction;

25 **FIG. 10A** illustrates an example of Angular intra prediction directions and the associated intra-prediction modes in JEM and BMS-1;

FIG. 10B illustrates an example of Angular intra prediction directions and the associated intra-prediction modes in VTM-2;

FIG. 10C illustrates an example of Angular intra prediction directions and the associated intra-prediction modes in VTM-3;

5 **FIG. 11** illustrates an example of Angular intra prediction directions and the associated intra-prediction modes in HEVC;

FIG. 12 illustrates an example of QTBT;

FIG. 13 illustrates an example of DC mode PDPC weights for (0, 0) and (1, 0) positions inside a 4x4 block;

10 **FIG. 14** illustrates an example of intra-predicting a block from reference samples of the main reference side;

FIG. 15 illustrates a method of intra-predicting a block of a picture according to an embodiment;

FIG. 16A illustrates an encoder device or a decoder device according to an embodiment;

15 **FIG. 16B** illustrates an encoder device or a decoder device according to an embodiment;

FIG. 17 illustrates an example of DC mode PDPC weights for (0, 0) and (1, 0) positions inside a 4x4 block;

FIG. 18 illustrates an example of intra-predicting a block of samples.

20 In the following identical reference signs refer to identical or at least functionally equivalent features if not explicitly specified otherwise.

DETAILED DESCRIPTION OF THE EMBODIMENTS

In the following description, reference is made to the accompanying figures, which form part of the disclosure, and which show, by way of illustration, specific aspects of embodiments of the disclosure or specific aspects in which embodiments of the present disclosure may be used.

25 It is understood that embodiments of the disclosure may be used in other aspects and comprise structural or logical changes not depicted in the figures. The following detailed description,

therefore, is not to be taken in a limiting sense, and the scope of the present disclosure is defined by the appended claims.

For instance, it is understood that a disclosure in connection with a described method may also hold true for a corresponding device or system configured to perform the method and vice versa. For example, if one or a plurality of specific method steps are described, a corresponding device may include one or a plurality of units, e.g., functional units, to perform the described one or plurality of method steps (e.g., one unit performing the one or plurality of steps, or a plurality of units each performing one or more of the plurality of steps), even if such one or more units are not explicitly described or illustrated in the figures. On the other hand, for example, if a specific apparatus is described based on one or a plurality of units, e.g., functional units, a corresponding method may include one step to perform the functionality of the one or plurality of units (e.g., one step performing the functionality of the one or plurality of units, or a plurality of steps each performing the functionality of one or more of the plurality of units), even if such one or plurality of steps are not explicitly described or illustrated in the figures. Further, it is understood that the features of the various exemplary embodiments and/or aspects described herein may be combined with each other, unless specifically noted otherwise.

Video coding typically refers to the processing of a sequence of pictures, which form the video or video sequence. Instead of the term “picture”, the term “frame” or “image” may be used as synonyms in the field of video coding. Video coding (or coding in general) comprises two parts, video encoding and video decoding. Video encoding is performed at the source side, typically comprising processing (e.g., by compression) the original video pictures to reduce the amount of data required for representing the video pictures (for more efficient storage and/or transmission). Video decoding is performed at the destination side and typically comprises the inverse processing compared to the encoder to reconstruct the video pictures. Embodiments referring to “coding” of video pictures (or pictures in general) shall be understood to relate to “encoding” or “decoding” of video pictures or respective video sequences. The combination of the encoding part and the decoding part is also referred to as CODEC (Coding and Decoding).

In case of lossless video coding, the original video pictures can be reconstructed, the reconstructed video pictures have the same quality as the original video pictures (assuming no transmission loss or other data loss during storage or transmission). In case of lossy video coding, further compression, e.g., by quantization, is performed, to reduce the amount of data representing the video pictures, which cannot be completely reconstructed at the decoder, the

quality of the reconstructed video pictures is lower or worse compared to the quality of the original video pictures.

Several video coding standards belong to the group of “lossy hybrid video codecs” (e.g. combine spatial and temporal prediction in the sample domain and 2D transform coding for applying quantization in the transform domain). Each picture of a video sequence is typically partitioned into a set of non-overlapping blocks, and the coding is typically performed on a block level. In other words, at the encoder the video is typically processed, i.e. encoded, on a block (video block) level, e.g., by using spatial (intra picture) prediction and/or temporal (inter picture) prediction to generate a prediction block, subtracting the prediction block from the current block (block currently processed/to be processed) to obtain a residual block, transforming the residual block and quantizing the residual block in the transform domain to reduce the amount of data to be transmitted (compression), whereas at the decoder the inverse processing compared to the encoder is applied to the encoded or compressed block to reconstruct the current block for representation. Furthermore, the encoder duplicates the decoder processing loop such that both will generate identical predictions (e.g., intra- and inter predictions) and/or re-constructions for processing, e.g. coding, the subsequent blocks.

In the following embodiments of a video coding system 10, a video encoder 20 and a video decoder 30 are described based on FIGS. 1 to 3.

FIG. 1A is a schematic block diagram illustrating an example coding system 10, e.g., a video coding system 10 (or short coding system 10) that may utilize techniques of this present application. Video encoder 20 (or short encoder 20) and video decoder 30 (or short decoder 30) of video coding system 10 represent examples of devices that may be configured to perform techniques in accordance with various examples described in the present application.

As shown in FIG. 1A, the coding system 10 comprises a source device 12 configured to provide encoded picture data 21 e.g., to a destination device 14 for decoding the encoded picture data 21.

The source device 12 comprises an encoder 20, and may additionally, optionally, comprise a picture source 16, a pre-processor (or pre-processing unit) 18, e.g., a picture pre-processor 18, and a communication interface or communication unit 22.

The picture source 16 may comprise or be any kind of picture capturing device, for example a camera for capturing a real-world picture, and/or any kind of a picture generating device, for example a computer-graphics processor for generating a computer animated picture, or any kind of other device for obtaining and/or providing a real-world picture, a computer generated picture (e.g., a screen content, a virtual reality (VR) picture) and/or any combination thereof (e.g., an augmented reality (AR) picture). The picture source may be any kind of memory or storage storing any of the aforementioned pictures.

In distinction to the pre-processor 18 and the processing performed by the pre-processing unit 18, the picture or picture data 17 may also be referred to as raw picture or raw picture data 17.

Pre-processor 18 is configured to receive the (raw) picture data 17 and to perform pre-processing on the picture data 17 to obtain a pre-processed picture 19 or pre-processed picture data 19. Pre-processing performed by the pre-processor 18 may, e.g., comprise trimming, color format conversion (e.g., from RGB to YCbCr), color correction, or de-noising. It can be understood that the pre-processing unit 18 may be optional component.

The video encoder 20 is configured to receive the pre-processed picture data 19 and provide encoded picture data 21 (further details will be described below, e.g., based on FIG. 2).

Communication interface 22 of the source device 12 may be configured to receive the encoded picture data 21 and to transmit the encoded picture data 21 (or any further processed version thereof) over communication channel 13 to another device, e.g., the destination device 14 or any other device, for storage or direct reconstruction.

The destination device 14 comprises a decoder 30 (e.g., a video decoder 30), and may additionally, i.e. optionally, comprise a communication interface or communication unit 28, a post-processor 32 (or post-processing unit 32) and a display device 34.

The communication interface 28 of the destination device 14 is configured receive the encoded picture data 21 (or any further processed version thereof), e.g., directly from the source device 12 or from any other source, e.g., a storage device, e.g., an encoded picture data storage device, and provide the encoded picture data 21 to the decoder 30.

The communication interface 22 and the communication interface 28 may be configured to transmit or receive the encoded picture data 21 or encoded data 13 via a direct communication

link between the source device 12 and the destination device 14, e.g., a direct wired or wireless connection, or via any kind of network, e.g., a wired or wireless network or any combination thereof, or any kind of private and public network, or any kind of combination thereof.

5 The communication interface 22 may be, e.g., configured to package the encoded picture data 21 into an appropriate format, e.g., packets, and/or process the encoded picture data using any kind of transmission encoding or processing for transmission over a communication link or communication network.

10 The communication interface 28, forming the counterpart of the communication interface 22, may be, e.g., configured to receive the transmitted data and process the transmission data using any kind of corresponding transmission decoding or processing and/or de-packaging to obtain the encoded picture data 21.

15 Both, communication interface 22 and communication interface 28 may be configured as unidirectional communication interfaces as indicated by the arrow for the communication channel 13 in FIG. 1A pointing from the source device 12 to the destination device 14, or bi-directional communication interfaces, and may be configured, e.g., to send and receive messages, e.g., to set up a connection, to acknowledge and exchange any other information related to the communication link and/or data transmission, e.g., encoded picture data transmission.

20 The decoder 30 is configured to receive the encoded picture data 21 and provide decoded picture data 31 or a decoded picture 31 (further details will be described below, e.g., based on FIG. 3 or FIG. 5).

25 The post-processor 32 of destination device 14 is configured to post-process the decoded picture data 31 (also called reconstructed picture data), e.g., the decoded picture 31, to obtain post-processed picture data 33, e.g., a post-processed picture 33. The post-processing performed by the post-processing unit 32 may comprise, e.g., color format conversion (e.g., from YCbCr to RGB), color correction, trimming, or re-sampling, or any other processing, e.g., for preparing the decoded picture data 31 for display, e.g., by display device 34.

30 The display device 34 of the destination device 14 is configured to receive the post-processed picture data 33 for displaying the picture, e.g., to a user or viewer. The display device 34 may be or comprise any kind of display for representing the reconstructed picture, e.g., an integrated

or external display or monitor. The displays may, e.g., comprise liquid crystal displays (LCD), organic light emitting diodes (OLED) displays, plasma displays, projectors, micro LED displays, liquid crystal on silicon (LCoS), digital light processor (DLP) or any kind of other display.

5 Although FIG. 1A depicts the source device 12 and the destination device 14 as separate devices, embodiments of devices may also comprise both or both functionalities, the source device 12 or corresponding functionality and the destination device 14 or corresponding functionality. In such embodiments the source device 12 or corresponding functionality and the destination device 14 or corresponding functionality may be implemented using the same
10 hardware and/or software or by separate hardware and/or software or any combination thereof.

As will be apparent for the skilled person based on the description, the existence and (exact) split of functionalities of the different units or functionalities within the source device 12 and/or destination device 14 as shown in FIG. 1A may vary depending on the actual device and application.

15 The encoder 20 (e.g., a video encoder 20) and the decoder 30 (e.g., a video decoder 30) each may be implemented as any of a variety of suitable circuitry as shown in FIG. 1B, such as one or more microprocessors, digital signal processors (DSPs), application-specific integrated circuits (ASICs), field-programmable gate arrays (FPGAs), discrete logic, hardware, or any combinations thereof. If the techniques are implemented partially in software, a device may
20 store instructions for the software in a suitable, non-transitory computer-readable storage medium and may execute the instructions in hardware using one or more processors to perform the techniques of this disclosure. Any of the foregoing (including hardware, software, a combination of hardware and software, etc.) may be considered to be one or more processors. Each of video encoder 20 and video decoder 30 may be included in one or more encoders or
25 decoders, either of which may be integrated as part of a combined encoder/decoder (CODEC) in a respective device.

Source device 12 and destination device 14 may comprise any of a wide range of devices, including any kind of handheld or stationary devices, e.g., notebook or laptop computers, mobile phones, smart phones, tablets or tablet computers, cameras, desktop computers, set-top
30 boxes, televisions, display devices, digital media players, video gaming consoles, video streaming devices (such as content services servers or content delivery servers), broadcast

receiver device, broadcast transmitter device, or the like and may use no or any kind of operating system. In some cases, the source device 12 and the destination device 14 may be equipped for wireless communication. Thus, the source device 12 and the destination device 14 may be wireless communication devices.

5 In some cases, video coding system 10 illustrated in FIG. 1A is merely an example and the techniques of the present application may apply to video coding settings (e.g., video encoding or video decoding) that do not necessarily include any data communication between the encoding and decoding devices. In other examples, data is retrieved from a local memory, streamed over a network, or the like. A video encoding device may encode and store data to
10 memory, and/or a video decoding device may retrieve and decode data from memory. In some examples, the encoding and decoding is performed by devices that do not communicate with one another, but simply encode data to memory and/or retrieve and decode data from memory.

FIG. 1B is an illustrative diagram of another example video coding system 40 including encoder 20 of FIG. 2 and/or decoder 30 of FIG. 3 according to an exemplary embodiment. The
15 system 40 can implement techniques in accordance with various examples described in the present application. In the illustrated implementation, video coding system 40 may include imaging device(s) 41, video encoder 100, video decoder 30 (and/or a video coder implemented via logic circuitry 47 of processing unit(s) 46), an antenna 42, one or more processor(s) 43, one or more memory store(s) 44, and/or a display device 45.

20 As illustrated, imaging device(s) 41, antenna 42, processing unit(s) 46, logic circuitry 47, video encoder 20, video decoder 30, processor(s) 43, memory store(s) 44, and/or display device 45 may be capable of communication with one another. As discussed, although illustrated with both video encoder 20 and video decoder 30, video coding system 40 may include only video encoder 20 or only video decoder 30 in various examples.

25 As shown, in some examples, video coding system 40 may include antenna 42. Antenna 42 may be configured to transmit or receive an encoded bitstream of video data, for example. Further, in some examples, video coding system 40 may include display device 45. Display device 45 may be configured to present video data. As shown, in some examples, logic circuitry 47 may be implemented via processing unit(s) 46. Processing unit(s) 46 may include
30 application-specific integrated circuit (ASIC) logic, graphics processor(s), general purpose processor(s), or the like. Video coding system 40 also may include optional processor(s) 43,

which may similarly include application-specific integrated circuit (ASIC) logic, graphics processor(s), general purpose processor(s), or the like. In some examples, logic circuitry 47 may be implemented via hardware, video coding dedicated hardware, or the like, and processor(s) 43 may implemented general purpose software, operating systems, or the like. In addition, memory store(s) 44 may be any type of memory such as volatile memory (e.g., Static Random Access Memory (SRAM), Dynamic Random Access Memory (DRAM), etc.) or non-volatile memory (e.g., flash memory, etc.), and so forth. In a non-limiting example, memory store(s) 44 may be implemented by cache memory. In some examples, logic circuitry 47 may access memory store(s) 44 (for implementation of an image buffer for example). In other examples, logic circuitry 47 and/or processing unit(s) 46 may include memory stores (e.g., cache or the like) for the implementation of an image buffer or the like.

In some examples, video encoder 20 implemented via logic circuitry may include an image buffer (e.g., via either processing unit(s) 46 or memory store(s) 44)) and a graphics processing unit (e.g., via processing unit(s) 46). The graphics processing unit may be communicatively coupled to the image buffer. The graphics processing unit may include video encoder 20 as implemented via logic circuitry 47 to embody the various modules as discussed with respect to FIG. 2 and/or any other encoder system or subsystem described herein. The logic circuitry may be configured to perform the various operations as discussed herein.

Video decoder 30 may be implemented in a similar manner as implemented via logic circuitry 47 to embody the various modules as discussed with respect to decoder 30 of FIG. 3 and/or any other decoder system or subsystem described herein. In some examples, video decoder 30 may be implemented via logic circuitry may include an image buffer (e.g., via either processing unit(s) 420 or memory store(s) 44)) and a graphics processing unit (e.g., via processing unit(s) 46). The graphics processing unit may be communicatively coupled to the image buffer. The graphics processing unit may include video decoder 30 as implemented via logic circuitry 47 to embody the various modules as discussed with respect to FIG. 3 and/or any other decoder system or subsystem described herein.

In some examples, antenna 42 of video coding system 40 may be configured to receive an encoded bitstream of video data. As discussed, the encoded bitstream may include data, indicators, index values, mode selection data, or the like associated with encoding a video frame as discussed herein, such as data associated with the coding partition (e.g., transform coefficients or quantized transform coefficients, optional indicators (as discussed), and/or data

defining the coding partition). Video coding system 40 may also include video decoder 30 coupled to antenna 42 and configured to decode the encoded bitstream. The display device 45 configured to present video frames.

For convenience of description, embodiments of the disclosure are described herein, for example, by reference to High-Efficiency Video Coding (HEVC) or to the reference software of Versatile Video coding (VVC), the next generation video coding standard developed by the Joint Collaboration Team on Video Coding (JCT-VC) of ITU-T Video Coding Experts Group (VCEG) and ISO/IEC Motion Picture Experts Group (MPEG). One of ordinary skill in the art will understand that embodiments of the disclosure are not limited to HEVC or VVC.

Encoder and Encoding Method

FIG. 2 shows a schematic block diagram of an example video encoder 20 that is configured to implement the techniques of the present application. In the example of FIG. 2, the video encoder 20 comprises an input 201 (or input interface 201), a residual calculation unit 204, a transform processing unit 206, a quantization unit 208, an inverse quantization unit 210, and inverse transform processing unit 212, a reconstruction unit 214, a loop filter unit 220, a decoded picture buffer (DPB) 230, a mode selection unit 260, an entropy encoding unit 270 and an output 272 (or output interface 272). The mode selection unit 260 may include an inter prediction unit 244, an intra prediction unit 254 and a partitioning unit 262. Inter prediction unit 244 may include a motion estimation unit and a motion compensation unit (not shown). A video encoder 20 as shown in FIG. 2 may also be referred to as hybrid video encoder or a video encoder according to a hybrid video codec.

The residual calculation unit 204, the transform processing unit 206, the quantization unit 208, the mode selection unit 260 may be referred to as forming a forward signal path of the encoder 20, whereas the inverse quantization unit 210, the inverse transform processing unit 212, the reconstruction unit 214, the buffer 216, the loop filter 220, the decoded picture buffer (DPB) 230, the inter prediction unit 244 and the intra-prediction unit 254 may be referred to as forming a backward signal path of the video encoder 20, wherein the backward signal path of the video encoder 20 corresponds to the signal path of the decoder (see video decoder 30 in FIG. 3). The inverse quantization unit 210, the inverse transform processing unit 212, the reconstruction unit 214, the loop filter 220, the decoded picture buffer (DPB) 230, the inter prediction unit 244 and

the intra-prediction unit 254 are also referred to forming the “built-in decoder” of video encoder 20.

Pictures & Picture Partitioning (Pictures & Blocks)

5 The encoder 20 may be configured to receive, e.g., via input 201, a picture 17 (or picture data 17), e.g., picture of a sequence of pictures forming a video or video sequence. The received picture or picture data may also be a pre-processed picture 19 (or pre-processed picture data 19). For sake of simplicity the following description refers to the picture 17. The picture 17 may also be referred to as current picture or picture to be coded (in particular in video coding
10 to distinguish the current picture from other pictures, e.g., previously encoded and/or decoded pictures of the same video sequence, i.e. the video sequence which also comprises the current picture).

A (digital) picture is or can be regarded as a two-dimensional array or matrix of samples with intensity values. A sample in the array may also be referred to as pixel (short form of picture
15 element) or a pel. The number of samples in horizontal and vertical direction (or axis) of the array or picture define the size and/or resolution of the picture. For representation of color, typically three color components are employed, i.e. the picture may be represented or include three sample arrays. In RGB format or color space a picture comprises a corresponding red, green and blue sample array. However, in video coding each pixel is typically represented in a
20 luminance and chrominance format or color space, e.g., YCbCr, which comprises a luminance component indicated by Y (sometimes also L is used instead) and two chrominance components indicated by Cb and Cr. The luminance (or short luma) component Y represents the brightness or grey level intensity (e.g., like in a grey-scale picture), while the two chrominance (or short chroma) components Cb and Cr represent the chromaticity or color
25 information components. Accordingly, a picture in YCbCr format comprises a luminance sample array of luminance sample values (Y), and two chrominance sample arrays of chrominance values (Cb and Cr). Pictures in RGB format may be converted or transformed into YCbCr format and vice versa, the process is also known as color transformation or conversion. If a picture is monochrome, the picture may comprise only a luminance sample
30 array. Accordingly, a picture may be, for example, an array of luma samples in monochrome

format or an array of luma samples and two corresponding arrays of chroma samples in 4:2:0, 4:2:2, and 4:4:4 color format.

Embodiments of the video encoder 20 may comprise a picture partitioning unit (not depicted in FIG. 2) configured to partition the picture 17 into a plurality of (typically non-overlapping) picture blocks 203. These blocks may also be referred to as root blocks, macro blocks (H.264/AVC) or coding tree blocks (CTB) or coding tree units (CTU) (H.265/HEVC and VVC). The picture partitioning unit may be configured to use the same block size for all pictures of a video sequence and the corresponding grid defining the block size, or to change the block size between pictures or subsets or groups of pictures, and partition each picture into the corresponding blocks.

In further embodiments, the video encoder may be configured to receive directly a block 203 of the picture 17, e.g., one, several or all blocks forming the picture 17. The picture block 203 may also be referred to as current picture block or picture block to be coded.

Like the picture 17, the picture block 203 again is or can be regarded as a two-dimensional array or matrix of samples with intensity values (sample values), although of smaller dimension than the picture 17. In other words, the block 203 may comprise, e.g., one sample array (e.g., a luma array in case of a monochrome picture 17, or a luma or chroma array in case of a color picture) or three sample arrays (e.g., a luma and two chroma arrays in case of a color picture 17) or any other number and/or kind of arrays depending on the color format applied. The number of samples in horizontal and vertical direction (or axis) of the block 203 define the size of block 203. Accordingly, a block may, for example, an $M \times N$ (M -column by N -row) array of samples, or an $M \times N$ array of transform coefficients.

Embodiments of the video encoder 20 as shown in FIG. 2 may be configured encode the picture 17 block by block, e.g., the encoding and prediction is performed per block 203.

Residual Calculation

The residual calculation unit 204 may be configured to calculate a residual block 205 (also referred to as residual 205) based on the picture block 203 and a prediction block 265 (further details about the prediction block 265 are provided later), e.g., by subtracting sample values of

the prediction block 265 from sample values of the picture block 203, sample by sample (pixel by pixel) to obtain the residual block 205 in the sample domain.

Transform

- 5 The transform processing unit 206 may be configured to apply a transform, e.g., a discrete cosine transform (DCT) or discrete sine transform (DST), on the sample values of the residual block 205 to obtain transform coefficients 207 in a transform domain. The transform coefficients 207 may also be referred to as transform residual coefficients and represent the residual block 205 in the transform domain.
- 10 The transform processing unit 206 may be configured to apply integer approximations of DCT/DST, such as the transforms specified for H.265/HEVC. Compared to an orthogonal DCT transform, such integer approximations are typically scaled by a certain factor. In order to preserve the norm of the residual block which is processed by forward and inverse transforms, additional scaling factors are applied as part of the transform process. The scaling factors are
- 15 typically chosen based on certain constraints like scaling factors being a power of two for shift operations, bit depth of the transform coefficients, tradeoff between accuracy and implementation costs, etc. Specific scaling factors are, for example, specified for the inverse transform, e.g., by inverse transform processing unit 212 (and the corresponding inverse transform, e.g., by inverse transform processing unit 312 at video decoder 30) and
- 20 corresponding scaling factors for the forward transform, e.g., by transform processing unit 206, at an encoder 20 may be specified accordingly.

Embodiments of the video encoder 20 (respectively transform processing unit 206) may be configured to output transform parameters, e.g., a type of transform or transforms, e.g., directly or encoded or compressed via the entropy encoding unit 270, so that, e.g., the video decoder

25 30 may receive and use the transform parameters for decoding.

Quantization

The quantization unit 208 may be configured to quantize the transform coefficients 207 to obtain quantized coefficients 209, e.g., by applying scalar quantization or vector quantization.

The quantized coefficients 209 may also be referred to as quantized transform coefficients 209 or quantized residual coefficients 209.

The quantization process may reduce the bit depth associated with some or all of the transform coefficients 207. For example, an n-bit transform coefficient may be rounded down to an m-bit Transform coefficient during quantization, where n is greater than m. The degree of quantization may be modified by adjusting a quantization parameter (QP). For example for scalar quantization, different scaling may be applied to achieve finer or coarser quantization. Smaller quantization step sizes correspond to finer quantization, whereas larger quantization step sizes correspond to coarser quantization. The applicable quantization step size may be indicated by a quantization parameter (QP). The quantization parameter may for example be an index to a predefined set of applicable quantization step sizes. For example, small quantization parameters may correspond to fine quantization (small quantization step sizes) and large quantization parameters may correspond to coarse quantization (large quantization step sizes) or vice versa. The quantization may include division by a quantization step size and a corresponding and/or the inverse dequantization, e.g., by inverse quantization unit 210, may include multiplication by the quantization step size. Embodiments according to some standards, e.g., HEVC, may be configured to use a quantization parameter to determine the quantization step size. Generally, the quantization step size may be calculated based on a quantization parameter using a fixed point approximation of an equation including division. Additional scaling factors may be introduced for quantization and dequantization to restore the norm of the residual block, which might get modified because of the scaling used in the fixed point approximation of the equation for quantization step size and quantization parameter. In one example implementation, the scaling of the inverse transform and dequantization might be combined. Alternatively, customized quantization tables may be used and signaled from an encoder to a decoder, e.g., in a bitstream. The quantization is a lossy operation, wherein the loss increases with increasing quantization step sizes.

Embodiments of the video encoder 20 (respectively quantization unit 208) may be configured to output quantization parameters (QP), e.g., directly or encoded via the entropy encoding unit 270, so that, e.g., the video decoder 30 may receive and apply the quantization parameters for decoding.

Inverse Quantization

The inverse quantization unit 210 is configured to apply the inverse quantization of the quantization unit 208 on the quantized coefficients to obtain dequantized coefficients 211, e.g., by applying the inverse of the quantization scheme applied by the quantization unit 208 based on or using the same quantization step size as the quantization unit 208. The dequantized coefficients 211 may also be referred to as dequantized residual coefficients 211 and correspond - although typically not identical to the transform coefficients due to the loss by quantization - to the transform coefficients 207.

10 *Inverse Transform*

The inverse transform processing unit 212 is configured to apply the inverse transform of the transform applied by the transform processing unit 206, e.g., an inverse discrete cosine transform (DCT) or inverse discrete sine transform (DST) or other inverse transforms, to obtain a reconstructed residual block 213 (or corresponding dequantized coefficients 213) in the sample domain. The reconstructed residual block 213 may also be referred to as transform block 213.

Reconstruction

The reconstruction unit 214 (e.g., adder or summer 214) is configured to add the transform block 213 (i.e. reconstructed residual block 213) to the prediction block 265 to obtain a reconstructed block 215 in the sample domain, e.g., by adding – sample by sample - the sample values of the reconstructed residual block 213 and the sample values of the prediction block 265.

25 *Filtering*

The loop filter unit 220 (or short “loop filter” 220), is configured to filter the reconstructed block 215 to obtain a filtered block 221, or in general, to filter reconstructed samples to obtain filtered samples. The loop filter unit is, e.g., configured to smooth pixel transitions, or

otherwise improve the video quality. The loop filter unit 220 may comprise one or more loop filters such as a de-blocking filter, a sample-adaptive offset (SAO) filter or one or more other filters, e.g., a bilateral filter, an adaptive loop filter (ALF), a sharpening, a smoothing filters or a collaborative filters, or any combination thereof. Although the loop filter unit 220 is shown in FIG. 2 as being an in loop filter, in other configurations, the loop filter unit 220 may be implemented as a post loop filter. The filtered block 221 may also be referred to as filtered reconstructed block 221. Decoded picture buffer 230 may store the reconstructed coding blocks after the loop filter unit 220 performs the filtering operations on the reconstructed coding blocks.

Embodiments of the video encoder 20 (respectively loop filter unit 220) may be configured to output loop filter parameters (such as sample adaptive offset information), e.g., directly or encoded via the entropy encoding unit 270, so that, e.g., a decoder 30 may receive and apply the same loop filter parameters or respective loop filters for decoding.

Decoded Picture Buffer

The decoded picture buffer (DPB) 230 may be a memory that stores reference pictures, or in general reference picture data, for encoding video data by video encoder 20. The DPB 230 may be formed by any of a variety of memory devices, such as dynamic random access memory (DRAM), including synchronous DRAM (SDRAM), magnetoresistive RAM (MRAM), resistive RAM (RRAM), or other types of memory devices. The decoded picture buffer (DPB) 230 may be configured to store one or more filtered blocks 221. The decoded picture buffer 230 may be further configured to store other previously filtered blocks, e.g., previously reconstructed and filtered blocks 221, of the same current picture or of different pictures, e.g., previously reconstructed pictures, and may provide complete previously reconstructed, i.e. decoded, pictures (and corresponding reference blocks and samples) and/or a partially reconstructed current picture (and corresponding reference blocks and samples), for example for inter prediction. The decoded picture buffer (DPB) 230 may be also configured to store one or more unfiltered reconstructed blocks 215, or in general unfiltered reconstructed samples, e.g., if the reconstructed block 215 is not filtered by loop filter unit 220, or any other further processed version of the reconstructed blocks or samples.

Mode Selection (Partitioning & Prediction)

The mode selection unit 260 comprises partitioning unit 262, inter-prediction unit 244 and intra-prediction unit 254, and is configured to receive or obtain original picture data, e.g., an original block 203 (current block 203 of the current picture 17), and reconstructed picture data, e.g., filtered and/or unfiltered reconstructed samples or blocks of the same (current) picture and/or from one or a plurality of previously decoded pictures, e.g., from decoded picture buffer 230 or other buffers (e.g., line buffer, not shown).. The reconstructed picture data is used as reference picture data for prediction, e.g., inter-prediction or intra-prediction, to obtain a prediction block 265 or predictor 265.

Mode selection unit 260 may be configured to determine or select a partitioning for a current block prediction mode (including no partitioning) and a prediction mode (e.g., an intra or inter prediction mode) and generate a corresponding prediction block 265, which is used for the calculation of the residual block 205 and for the reconstruction of the reconstructed block 215.

Embodiments of the mode selection unit 260 may be configured to select the partitioning and the prediction mode (e.g., from those supported by or available for mode selection unit 260), which provide the best match or in other words the minimum residual (minimum residual means better compression for transmission or storage), or a minimum signaling overhead (minimum signaling overhead means better compression for transmission or storage), or which considers or balances both. The mode selection unit 260 may be configured to determine the partitioning and prediction mode based on rate distortion optimization (RDO), i.e. select the prediction mode which provides a minimum rate distortion. Terms like “best”, “minimum”, “optimum” etc. in this context do not necessarily refer to an overall “best”, “minimum”, “optimum”, etc. but may also refer to the fulfillment of a termination or selection criterion like a value exceeding or falling below a threshold or other constraints leading potentially to a “sub-optimum selection” but reducing complexity and processing time.

In other words, the partitioning unit 262 may be configured to partition the block 203 into smaller block partitions or sub-blocks (which form again blocks), e.g., iteratively using quad-tree-partitioning (QT), binary partitioning (BT) or triple-tree-partitioning (TT) or any combination thereof, and to perform, e.g., the prediction for each of the block partitions or sub-blocks, wherein the mode selection comprises the selection of the tree-structure of the

partitioned block 203 and the prediction modes are applied to each of the block partitions or sub-blocks.

In the following the partitioning (e.g., by partitioning unit 260) and prediction processing (by inter-prediction unit 244 and intra-prediction unit 254) performed by an example video encoder
5 20 will be explained in more detail.

Partitioning

The partitioning unit 262 may partition (or split) a current block 203 into smaller partitions, e.g., smaller blocks of square or rectangular size. These smaller blocks (which may also be
10 referred to as sub-blocks) may be further partitioned into even smaller partitions. This is also referred to tree-partitioning or hierarchical tree-partitioning, wherein a root block, e.g., at root tree-level 0 (hierarchy-level 0, depth 0), may be recursively partitioned, e.g., partitioned into two or more blocks of a next lower tree-level, e.g., nodes at tree-level 1 (hierarchy-level 1, depth 1), wherein these blocks may be again partitioned into two or more blocks of a next lower
15 level, e.g., tree-level 2 (hierarchy-level 2, depth 2), etc. until the partitioning is terminated, e.g., because a termination criterion is fulfilled, e.g., a maximum tree depth or minimum block size is reached. Blocks which are not further partitioned are also referred to as leaf-blocks or leaf nodes of the tree. A tree using partitioning into two partitions is referred to as binary-tree (BT), a tree using partitioning into three partitions is referred to as ternary-tree (TT), and a tree using
20 partitioning into four partitions is referred to as quad-tree (QT).

As mentioned before, the term “block” as used herein may be a portion, in particular a square or rectangular portion, of a picture. With reference, for example, to HEVC and VVC, the block may be or correspond to a coding tree unit (CTU), a coding unit (CU), prediction unit (PU), and transform unit (TU) and/or to the corresponding blocks, e.g., a coding tree block (CTB), a
25 coding block (CB), a transform block (TB) or prediction block (PB).

For example, a coding tree unit (CTU) may be or comprise a CTB of luma samples, two corresponding CTBs of chroma samples of a picture that has three sample arrays, or a CTB of samples of a monochrome picture or a picture that is coded using three separate color planes and syntax structures used to code the samples. Correspondingly, a coding tree block (CTB)
30 may be an $N \times N$ block of samples for some value of N such that the division of a component

into CTBs is a partitioning. A coding unit (CU) may be or comprise a coding block of luma samples, two corresponding coding blocks of chroma samples of a picture that has three sample arrays, or a coding block of samples of a monochrome picture or a picture that is coded using three separate color planes and syntax structures used to code the samples. Correspondingly a coding block (CB) may be an $M \times N$ block of samples for some values of M and N such that the division of a CTB into coding blocks is a partitioning.

In embodiments, e.g., according to HEVC, a coding tree unit (CTU) may be split into CUs by using a quad-tree structure denoted as coding tree. The decision whether to code a picture area using inter-picture (temporal) or intra-picture (spatial) prediction is made at the CU level. Each CU can be further split into one, two or four PUs according to the PU splitting type. Inside one PU, the same prediction process is applied and the relevant information is transmitted to the decoder on a PU basis. After obtaining the residual block by applying the prediction process based on the PU splitting type, a CU can be partitioned into transform units (TUs) according to another quadtree structure similar to the coding tree for the CU.

In embodiments, e.g., according to the latest video coding standard currently in development, which is referred to as Versatile Video Coding (VVC), Quad-tree and binary tree (QTBT) partitioning is used to partition a coding block. In the QTBT block structure, a CU can have either a square or rectangular shape. For example, a coding tree unit (CTU) is first partitioned by a quadtree structure. The quadtree leaf nodes are further partitioned by a binary tree or ternary (or triple) tree structure. The partitioning tree leaf nodes are called coding units (CUs), and that segmentation is used for prediction and transform processing without any further partitioning. This means that the CU, PU and TU have the same block size in the QTBT coding block structure. In parallel, multiple partition, for example, triple tree partition was also proposed to be used together with the QTBT block structure.

In one example, the mode selection unit 260 of video encoder 20 may be configured to perform any combination of the partitioning techniques described herein.

As described above, the video encoder 20 is configured to determine or select the best or an optimum prediction mode from a set of (pre-determined) prediction modes. The set of prediction modes may comprise, e.g., intra-prediction modes and/or inter-prediction modes.

Intra-Prediction

The set of intra-prediction modes may comprise 35 different intra-prediction modes, e.g., non-directional modes like DC (or mean) mode and planar mode, or directional modes, e.g., as defined in HEVC, or may comprise 67 different intra-prediction modes, e.g., non-directional modes like DC (or mean) mode and planar mode, or directional modes, e.g., as defined for VVC.

The intra-prediction unit 254 is configured to use reconstructed samples of neighboring blocks of the same current picture to generate an intra-prediction block 265 according to an intra-prediction mode of the set of intra-prediction modes.

The intra prediction unit 254 (or in general the mode selection unit 260) is further configured to output intra-prediction parameters (or in general information indicative of the selected intra prediction mode for the block) to the entropy encoding unit 270 in form of syntax elements 266 for inclusion into the encoded picture data 21, so that, e.g., the video decoder 30 may receive and use the prediction parameters for decoding.

Inter-Prediction

The set of (or possible) inter-prediction modes depends on the available reference pictures (i.e. previous at least partially decoded pictures, e.g., stored in DBP 230) and other inter-prediction parameters, e.g., whether the whole reference picture or only a part, e.g., a search window area around the area of the current block, of the reference picture is used for searching for a best matching reference block, and/or e.g., whether pixel interpolation is applied, e.g., half/semi-pel and/or quarter-pel interpolation, or not.

Additional to the above prediction modes, skip mode and/or direct mode may be applied.

The inter prediction unit 244 may include a motion estimation (ME) unit and a motion compensation (MC) unit (both not shown in FIG. 2). The motion estimation unit may be configured to receive or obtain the picture block 203 (current picture block 203 of the current picture 17) and a decoded picture 231, or at least one or a plurality of previously reconstructed blocks, e.g., reconstructed blocks of one or a plurality of other/different previously decoded pictures 231, for motion estimation. E.g., a video sequence may comprise the current picture

and the previously decoded pictures 231, or in other words, the current picture and the previously decoded pictures 231 may be part of or form a sequence of pictures forming a video sequence.

The encoder 20 may, e.g., be configured to select a reference block from a plurality of reference blocks of the same or different pictures of the plurality of other pictures and provide a reference picture (or reference picture index) and/or an offset (spatial offset) between the position (x, y coordinates) of the reference block and the position of the current block as inter prediction parameters to the motion estimation unit. This offset is also called motion vector (MV).

The motion compensation unit is configured to obtain, e.g., receive, an inter prediction parameter and to perform inter prediction based on or using the inter prediction parameter to obtain an inter prediction block 265. Motion compensation, performed by the motion compensation unit, may involve fetching or generating the prediction block based on the motion/block vector determined by motion estimation, possibly performing interpolations to sub-pixel precision. Interpolation filtering may generate additional pixel samples from known pixel samples, thus potentially increasing the number of candidate prediction blocks that may be used to code a picture block. Upon receiving the motion vector for the PU of the current picture block, the motion compensation unit may locate the prediction block to which the motion vector points in one of the reference picture lists.

Motion compensation unit may also generate syntax elements associated with the blocks and the video slice for use by video decoder 30 in decoding the picture blocks of the video slice.

Entropy Coding

The entropy encoding unit 270 is configured to apply, for example, an entropy encoding algorithm or scheme (e.g., a variable length coding (VLC) scheme, an context adaptive VLC scheme (CAVLC), an arithmetic coding scheme, a binarization, a context adaptive binary arithmetic coding (CABAC), syntax-based context-adaptive binary arithmetic coding (SBAC), probability interval partitioning entropy (PIPE) coding or another entropy encoding methodology or technique) or bypass (no compression) on the quantized coefficients 209, inter prediction parameters, intra prediction parameters, loop filter parameters and/or other syntax elements to obtain encoded picture data 21 which can be output via the output 272, e.g., in the

form of an encoded bitstream 21, so that, e.g., the video decoder 30 may receive and use the parameters for decoding. The encoded bitstream 21 may be transmitted to video decoder 30, or stored in a memory for later transmission or retrieval by video decoder 30.

Other structural variations of the video encoder 20 can be used to encode the video stream. For example, a non-transform based encoder 20 can quantize the residual signal directly without the transform processing unit 206 for certain blocks or frames. In another implementation, an encoder 20 can have the quantization unit 208 and the inverse quantization unit 210 combined into a single unit.

10 *Decoder and Decoding Method*

FIG. 3 shows an example of a video decoder 30 that is configured to implement the techniques of this present application. The video decoder 30 is configured to receive encoded picture data 21 (e.g., encoded bitstream 21), e.g., encoded by encoder 20, to obtain a decoded picture 331. The encoded picture data or bitstream comprises information for decoding the encoded picture data, e.g., data that represents picture blocks of an encoded video slice and associated syntax elements.

In the example of FIG. 3, the decoder 30 comprises an entropy decoding unit 304, an inverse quantization unit 310, an inverse transform processing unit 312, a reconstruction unit 314 (e.g., a summer 314), a loop filter 320, a decoded picture buffer (DPB) 330, an inter prediction unit 344 and an intra prediction unit 354. Inter prediction unit 344 may be or include a motion compensation unit. Video decoder 30 may, in some examples, perform a decoding pass generally reciprocal to the encoding pass described with respect to video encoder 100 from FIG. 2.

As explained with regard to the encoder 20, the inverse quantization unit 210, the inverse transform processing unit 212, the reconstruction unit 214 the loop filter 220, the decoded picture buffer (DPB) 230, the inter prediction unit 344 and the intra prediction unit 354 are also referred to as forming the “built-in decoder” of video encoder 20. Accordingly, the inverse quantization unit 310 may be identical in function to the inverse quantization unit 110, the inverse transform processing unit 312 may be identical in function to the inverse transform processing unit 212, the reconstruction unit 314 may be identical in function to reconstruction

unit 214, the loop filter 320 may be identical in function to the loop filter 220, and the decoded picture buffer 330 may be identical in function to the decoded picture buffer 230. Therefore, the explanations provided for the respective units and functions of the video 20 encoder apply correspondingly to the respective units and functions of the video decoder 30.

5

Entropy Decoding

The entropy decoding unit 304 is configured to parse the bitstream 21 (or in general encoded picture data 21) and perform, for example, entropy decoding to the encoded picture data 21 to obtain, e.g., quantized coefficients 309 and/or decoded coding parameters (not shown in FIG. 3), e.g., any or all of inter prediction parameters (e.g., reference picture index and motion vector), intra prediction parameter (e.g., intra prediction mode or index), transform parameters, quantization parameters, loop filter parameters, and/or other syntax elements. Entropy decoding unit 304 maybe configured to apply the decoding algorithms or schemes corresponding to the encoding schemes as described with regard to the entropy encoding unit 270 of the encoder 20. Entropy decoding unit 304 may be further configured to provide inter prediction parameters, intra prediction parameter and/or other syntax elements to the mode selection unit 360 and other parameters to other units of the decoder 30. Video decoder 30 may receive the syntax elements at the video slice level and/or the video block level.

Inverse Quantization

The inverse quantization unit 310 may be configured to receive quantization parameters (QP) (or in general information related to the inverse quantization) and quantized coefficients from the encoded picture data 21 (e.g., by parsing and/or decoding, e.g., by entropy decoding unit 304) and to apply based on the quantization parameters an inverse quantization on the decoded quantized coefficients 309 to obtain dequantized coefficients 311, which may also be referred to as transform coefficients 311. The inverse quantization process may include use of a quantization parameter determined by video encoder 20 for each video block in the video slice to determine a degree of quantization and, likewise, a degree of inverse quantization that should be applied.

Inverse Transform

Inverse transform processing unit 312 may be configured to receive dequantized coefficients 311, also referred to as transform coefficients 311, and to apply a transform to the dequantized coefficients 311 in order to obtain reconstructed residual blocks 213 in the sample domain. The reconstructed residual blocks 213 may also be referred to as transform blocks 313. The transform may be an inverse transform, e.g., an inverse DCT, an inverse DST, an inverse integer transform, or a conceptually similar inverse transform process. The inverse transform processing unit 312 may be further configured to receive transform parameters or corresponding information from the encoded picture data 21 (e.g., by parsing and/or decoding, e.g., by entropy decoding unit 304) to determine the transform to be applied to the dequantized coefficients 311.

Reconstruction

The reconstruction unit 314 (e.g., adder or summer 314) may be configured to add the reconstructed residual block 313, to the prediction block 365 to obtain a reconstructed block 315 in the sample domain, e.g., by adding the sample values of the reconstructed residual block 313 and the sample values of the prediction block 365.

Filtering

The loop filter unit 320 (either in the coding loop or after the coding loop) is configured to filter the reconstructed block 315 to obtain a filtered block 321, e.g., to smooth pixel transitions, or otherwise improve the video quality. The loop filter unit 320 may comprise one or more loop filters such as a de-blocking filter, a sample-adaptive offset (SAO) filter or one or more other filters, e.g., a bilateral filter, an adaptive loop filter (ALF), a sharpening, a smoothing filters or a collaborative filters, or any combination thereof. Although the loop filter unit 320 is shown in FIG. 3 as being an in loop filter, in other configurations, the loop filter unit 320 may be implemented as a post loop filter.

Decoded Picture Buffer

The decoded video blocks 321 of a picture are then stored in decoded picture buffer 330, which stores the decoded pictures 331 as reference pictures for subsequent motion compensation for other pictures and/or for output respectively display.

The decoder 30 is configured to output the decoded picture 311, e.g., via output 312, for presentation or viewing to a user.

Prediction

The inter prediction unit 344 may be identical to the inter prediction unit 244 (in particular to the motion compensation unit) and the intra prediction unit 354 may be identical to the inter prediction unit 254 in function, and performs split or partitioning decisions and prediction based on the partitioning and/or prediction parameters or respective information received from the encoded picture data 21 (e.g., by parsing and/or decoding, e.g., by entropy decoding unit 304). Mode selection unit 360 may be configured to perform the prediction (intra or inter prediction) per block based on reconstructed pictures, blocks or respective samples (filtered or unfiltered) to obtain the prediction block 365.

When the video slice is coded as an intra coded (I) slice, intra prediction unit 354 of mode selection unit 360 is configured to generate prediction block 365 for a picture block of the current video slice based on a signaled intra prediction mode and data from previously decoded blocks of the current picture. When the video picture is coded as an inter coded (i.e., B, or P) slice, inter prediction unit 344 (e.g., motion compensation unit) of mode selection unit 360 is configured to produce prediction blocks 365 for a video block of the current video slice based on the motion vectors and other syntax elements received from entropy decoding unit 304. For inter prediction, the prediction blocks may be produced from one of the reference pictures within one of the reference picture lists. Video decoder 30 may construct the reference frame lists, List 0 and List 1, using default construction techniques based on reference pictures stored in DPB 330.

Mode selection unit 360 is configured to determine the prediction information for a video block of the current video slice by parsing the motion vectors and other syntax elements, and uses the prediction information to produce the prediction blocks for the current video block being decoded. For example, the mode selection unit 360 uses some of the received syntax elements to determine a prediction mode (e.g., intra or inter prediction) used to code the video blocks of the video slice, an inter prediction slice type (e.g., B slice, P slice, or GPB slice), construction information for one or more of the reference picture lists for the slice, motion vectors for each inter encoded video block of the slice, inter prediction status for each inter coded video block of the slice, and other information to decode the video blocks in the current video slice.

Other variations of the video decoder 30 can be used to decode the encoded picture data 21. For example, the decoder 30 can produce the output video stream without the loop filtering unit 320. For example, a non-transform based decoder 30 can inverse-quantize the residual signal directly without the inverse-transform processing unit 312 for certain blocks or frames. In another implementation, the video decoder 30 can have the inverse-quantization unit 310 and the inverse-transform processing unit 312 combined into a single unit.

FIG. 4 is a schematic diagram of a video coding device 400 according to an embodiment of the disclosure. The video coding device 400 is suitable for implementing the disclosed embodiments as described herein. In an embodiment, the video coding device 400 may be a decoder such as video decoder 30 of FIG. 1A or an encoder such as video encoder 20 of FIG. 1A.

The video coding device 400 comprises ingress ports 410 (or input ports 410) and receiver units (Rx) 420 for receiving data; a processor, logic unit, or central processing unit (CPU) 430 to process the data; transmitter units (Tx) 440 and egress ports 450 (or output ports 450) for transmitting the data; and a memory 460 for storing the data. The video coding device 400 may also comprise optical-to-electrical (OE) components and electrical-to-optical (EO) components coupled to the ingress ports 410, the receiver units 420, the transmitter units 440, and the egress ports 450 for egress or ingress of optical or electrical signals.

The processor 430 is implemented by hardware and software. The processor 430 may be implemented as one or more CPU chips, cores (e.g., as a multi-core processor), FPGAs, ASICs, and DSPs. The processor 430 is in communication with the ingress ports 410, receiver units 420, transmitter units 440, egress ports 450, and memory 460. The processor 430 comprises a

coding module 470. The coding module 470 implements the disclosed embodiments described above. For instance, the coding module 470 implements, processes, prepares, or provides the various coding operations. The inclusion of the coding module 470 therefore provides a substantial improvement to the functionality of the video coding device 400 and effects a transformation of the video coding device 400 to a different state. Alternatively, the coding module 470 is implemented as instructions stored in the memory 460 and executed by the processor 430.

The memory 460 may comprise one or more disks, tape drives, and solid-state drives and may be used as an over-flow data storage device, to store programs when such programs are selected for execution, and to store instructions and data that are read during program execution. The memory 460 may be, for example, volatile and/or non-volatile and may be a read-only memory (ROM), random access memory (RAM), ternary content-addressable memory (TCAM), and/or static random-access memory (SRAM).

FIG. 5 is a simplified block diagram of an apparatus 500 that may be used as either or both of the source device 12 and the destination device 14 from FIG. 1A according to an exemplary embodiment. The apparatus 500 can implement techniques of this present application described above. The apparatus 500 can be in the form of a computing system including multiple computing devices, or in the form of a single computing device, for example, a mobile phone, a tablet computer, a laptop computer, a notebook computer, a desktop computer, and the like.

A processor 502 in the apparatus 500 can be a central processing unit. Alternatively, the processor 502 can be any other type of device, or multiple devices, capable of manipulating or processing information now-existing or hereafter developed. Although the disclosed implementations can be practiced with a single processor as shown, e.g., the processor 502, advantages in speed and efficiency can be achieved using more than one processor.

A memory 504 in the apparatus 500 can be a read only memory (ROM) device or a random access memory (RAM) device in an implementation. Any other suitable type of storage device can be used as the memory 504. The memory 504 can include code and data 506 that is accessed by the processor 502 using a bus 512. The memory 504 can further include an operating system 508 and application programs 510, the application programs 510 including at least one program that permits the processor 502 to perform the methods described here. For example, the application programs 510 can include applications 1 through N, which further include a video

coding application that performs the methods described here. The apparatus 500 can also include additional memory in the form of a secondary storage 514, which can, for example, be a memory card used with a mobile computing device. Because the video communication sessions may contain a significant amount of information, they can be stored in whole or in part in the secondary storage 514 and loaded into the memory 504 as needed for processing.

The apparatus 500 can also include one or more output devices, such as a display 518. The display 518 may be, in one example, a touch sensitive display that combines a display with a touch sensitive element that is operable to sense touch inputs. The display 518 can be coupled to the processor 502 via the bus 512. Other output devices that permit a user to program or otherwise use the apparatus 500 can be provided in addition to or as an alternative to the display 518. When the output device is or includes a display, the display can be implemented in various ways, including by a liquid crystal display (LCD), a cathode-ray tube (CRT) display, a plasma display or light emitting diode (LED) display, such as an organic LED (OLED) display.

The apparatus 500 can also include or be in communication with an image-sensing device 520, for example a camera, or any other image-sensing device 520 now existing or hereafter developed that can sense an image such as the image of a user operating the apparatus 500. The image-sensing device 520 can be positioned such that it is directed toward the user operating the apparatus 500. In an example, the position and optical axis of the image-sensing device 520 can be configured such that the field of vision includes an area that is directly adjacent to the display 518 and from which the display 518 is visible.

The apparatus 500 can also include or be in communication with a sound-sensing device 522, for example a microphone, or any other sound-sensing device now existing or hereafter developed that can sense sounds near the apparatus 500. The sound-sensing device 522 can be positioned such that it is directed toward the user operating the apparatus 500 and can be configured to receive sounds, for example, speech or other utterances, made by the user while the user operates the apparatus 500.

Although FIG. 5 depicts the processor 502 and the memory 504 of the apparatus 500 as being integrated into a single unit, other configurations can be utilized. The operations of the processor 502 can be distributed across multiple machines (each machine having one or more of processors) that can be coupled directly or across a local area or other network. The memory 504 can be distributed across multiple machines such as a network-based memory or memory

in multiple machines performing the operations of the apparatus 500. Although depicted here as a single bus, the bus 512 of the apparatus 500 can be composed of multiple buses. Further, the secondary storage 514 can be directly coupled to the other components of the apparatus 500 or can be accessed via a network and can comprise a single integrated unit such as a memory card or multiple units such as multiple memory cards. The apparatus 500 can thus be implemented in a wide variety of configurations.

Position-dependent prediction combination (PDPC)

In recent development of video coding, more sophisticated techniques and schemes for prediction have emerged.

One such technique is Position-dependent prediction combination (PDPC). PDPC is a scheme that has been devised to address certain issues and improve intra prediction. In the PDPC scheme, an image or video coder determines a value of a predicted sample based on filtered reference samples, unfiltered reference samples, and the position of the predicted sample within a current block. Use of the PDPC scheme may be associated with coding efficiency gains. For instance, the same amount of video data may be encoded using fewer bits.

Video coding schemes such as H.264/AVC and HEVC are designed along the successful principle of block-based hybrid video coding. Using this principle a picture is first partitioned into blocks and then each block is predicted by using intra-picture or inter-picture prediction.

Several video coding standards since H.261 belong to the group of “lossy hybrid video codecs” (i.e. combine spatial and temporal prediction in the sample domain and 2D transform coding for applying quantization in the transform domain). Each picture of a video sequence is typically partitioned into a set of non-overlapping blocks and the coding is typically performed on a block level. In other words, at the encoder the video is typically processed, i.e. encoded, on a block (picture block) level, e.g., by using spatial (intra picture) prediction and temporal (inter picture) prediction to generate a prediction block, subtracting the prediction block from the current block (block currently processed/to be processed) to obtain a residual block, transforming the residual block and quantizing the residual block in the transform domain to reduce the amount of data to be transmitted (compression), whereas at the decoder the inverse processing compared to the encoder is partially applied to the encoded or compressed block to

reconstruct the current block for representation. Furthermore, the encoder duplicates the decoder processing loop such that both will generate identical predictions (e.g., intra- and inter predictions) and/or re-constructions for processing, i.e. coding, the subsequent blocks.

As used herein, the term “block” may a portion of a picture or a frame. For convenience of description, embodiments of the disclosure are described herein in reference to High-Efficiency Video Coding (HEVC) or the reference software of Versatile video coding (VVC), developed by the Joint Collaboration Team on Video Coding (JCT-VC) of ITU-T Video Coding Experts Group (VCEG) and ISO/IEC Motion Picture Experts Group (MPEG). One of ordinary skill in the art will understand that embodiments of the disclosure are not limited to HEVC or VVC. It may refer to a CU, PU, and TU. In HEVC, a CTU is split into CUs by using a quad-tree structure denoted as coding tree. The decision whether to code a picture area using inter-picture (temporal) or intra-picture (spatial) prediction is made at the CU level. Each CU can be further split into one, two or four PUs according to the PU splitting type. Inside one PU, the same prediction process is applied and the relevant information is transmitted to the decoder on a PU basis. After obtaining the residual block by applying the prediction process based on the PU splitting type, a CU can be partitioned into transform units (TUs) according to another quadtree structure similar to the coding tree for the CU. In the newest development of the video compression technical, Quad-tree and binary tree (QTBT) partitioning is used to partition a coding block. In the QTBT block structure, a CU can have either a square or rectangular shape. For example, a coding tree unit (CTU) is first partitioned by a quadtree structure. The quadtree leaf nodes are further partitioned by a binary tree structure. The binary tree leaf nodes are called coding units (CUs), and that segmentation is used for prediction and transform processing without any further partitioning. This means that the CU, PU and TU have the same block size in the QTBT coding block structure. In parallel, multiple partition, for example, triple tree partition was also proposed to be used together with the QTBT block structure.

ITU-T VCEG (Q6/16) and ISO/IEC MPEG (JTC 1/SC 29/WG 11) are studying the potential need for standardization of future video coding technology with a compression capability that significantly exceeds that of the current HEVC standard (including its current extensions and near-term extensions for screen content coding and high-dynamic-range coding). The groups are working together on this exploration activity in a joint collaboration effort known as the Joint Video Exploration Team (JVET) to evaluate compression technology designs proposed by their experts in this area.

In an example, for directional intra prediction, intra prediction modes are available representing different prediction angles from diagonal-up to diagonal-down. For definition of the prediction angles, an offset value p_{ang} on a 32-sample grid is defined. The association of p_{ang} to the corresponding intra prediction mode is visualized in FIG. 6 for the vertical prediction modes.

5 For the horizontal prediction modes the scheme is flipped to vertical direction and the p_{ang} values are assigned accordingly. As stated above, angular prediction modes are available for all applicable intra prediction block sizes. They may use the same 32-sample grid for the definition of the prediction angles. The distribution of the p_{ang} values over the 32-sample grid in FIG. 6 reveals an increased resolution of the prediction angles around the vertical direction
10 and a coarser resolution of the prediction angles towards the diagonal directions. The same applies to the horizontal directions. This design stems from the observation that in lots of video content, approximately horizontal and vertical structures play an important role compared to diagonal structures.

In an example, while for the horizontal and vertical prediction directions, the selection of
15 samples to be used for prediction is straightforward, this task requires more effort in case of angular prediction. For modes 11–25, when predicting the current block B_c from the set of prediction samples p_{ref} (also known as main reference side) in an angular direction, samples of both, the vertical and the horizontal part of p_{ref} can be involved. Since the determination of the location of the respective samples on either of the branches of p_{ref} requires some computational
20 effort, a unified one-dimensional prediction reference has been designed for HEVC intra prediction. The scheme is visualized in FIG. 7. Before performing the actual prediction operation, the set of reference samples p_{ref} is mapped to a 1-dimensional vector $p_{1,\text{ref}}$. The projection which is used for the mapping depends on the direction indicated by the intra prediction angle of the respective intra prediction mode. Only reference samples from the part
25 of p_{ref} which is to be used for prediction are mapped to $p_{1,\text{ref}}$. The actual mapping of the reference samples to $p_{1,\text{ref}}$ for each angular prediction mode is depicted in FIGS. 8 and 9 for horizontal and vertical angular prediction directions, respectively. The reference samples set $p_{1,\text{ref}}$ is constructed once for the predicted block. The prediction is then derived from two neighboring reference samples in the set as detailed below. As can be seen from FIGS. 8 and 9
30 the 1-dimensional reference sample set is not completely filled for all intra prediction modes. Only the locations which are in the projection range for the corresponding intra prediction direction are included in the set.

The prediction for both, horizontal and vertical prediction modes is performed in the same manner with only swapping the x and y coordinates of the block. The prediction from $p_{1,\text{ref}}$ is performed in 1/32-pel accuracy. Depending on the value of the angle parameter p_{ang} , a sample offset i_{idx} in $p_{1,\text{ref}}$ and a weighting factor i_{fact} for a sample at position (x, y) are determined. Here, the derivation for the vertical modes is provided. The derivation for the horizontal modes follows accordingly, swapping x and y .

$$i_{\text{idx}} = (y + 1) \cdot \frac{p_{\text{ang}}}{32}, \quad i_{\text{fact}} = [(y + 1) \cdot p_{\text{ang}}] \bmod 32.$$

If i_{fact} is not equal to 0, i.e. the prediction does not fall exactly on a full sample location in $p_{1,\text{ref}}$, a linear weighting between the two neighboring sample locations in $p_{1,\text{ref}}$ is performed as

$$\mathbf{B}_c(x, y) = \frac{32 - i_{\text{fact}}}{32} \cdot p_{1,\text{ref}}(x + i_{\text{idx}} + 1) + \frac{i_{\text{fact}}}{32} \cdot p_{1,\text{ref}}(x + i_{\text{idx}} + 2),$$

with $0 \leq x, y < N_c$. It should be noted that the values of i_{idx} and i_{fact} only depend on y , and therefore only need to be calculated once per row (for vertical prediction modes).

The VTM-1.0 (Versatile Test Model) uses 35 Intra modes whereas the BMS (Benchmark Set) uses 67 Intra modes. Intra-prediction is a mechanism used in many video coding frameworks to increase compression efficiency in the cases where only a given frame can be involved.

FIG. 10A shows an example of 67 intra prediction modes, e.g., as proposed for VVC, the plurality of intra prediction modes of 67 intra prediction modes comprising: planar mode (index 0), dc mode (index 1), and angular modes with indices 2 to 66, wherein the left bottom angular mode in FIG. 10A refers to index 2 and the numbering of the indices being incremented until index 66 being the top right most angular mode of FIG. 10A.

As shown in FIG. 10A, the latest version of JEM has some modes corresponding to skew intra prediction directions. For any of these modes, to predict samples within a block interpolation of a set of neighboring reference samples should be performed, if a corresponding position within a block side is fractional. HEVC and VVC uses linear interpolation between two adjacent reference samples. JEM uses more sophisticated 4-tap interpolation filters. Filter coefficients are selected to be either Gaussian or Cubic ones depending on the width or on the height value. Decision on whether to use width or height is harmonized with the decision on

main reference side selection: when intra prediction mode is greater or equal to diagonal mode, top side of reference samples is selected to be the main reference side and width value is selected to determine interpolation filter in use. Otherwise, main side reference is selected from the left side of the block and height controls the filter selection process. Specifically, if selected side length is smaller than or equal to 8 samples, Cubic interpolation 4 tap is applied. Otherwise, interpolation filter is a 4-tap Gaussian one.

Specific filter coefficient used in JEM are given in Table 1. Predicted sample is calculated by convoluting with coefficients selected from Table 1 according to subpixel offset and filter type as follows:

$$s(x) = \left(\sum_{i=0}^{i<4} (\text{ref}_{i+x} \cdot c_i) + 128 \right) \gg 8$$

In this equation, “ $\gg$ ” indicates a bitwise shift-right operation.

If the Cubic filter is selected, the predicted sample is further clipped to the allowed range of values, that is either defined in sequence parameter set (SPS) or derived from the bit depth of the selected component.

A SPS may specify features and activated tools used in a coded video sequence. In contrast to the video parameter set (VPS), which concerns the whole bitstream, the SPS information applies only for a layer specified by a layer identifier. For instance, features specified in the SPS include the color format and bit depth as well as the sample resolution of coded pictures.

Table 1. Intra prediction interpolation filters used in JEM

An intra-predicted sample is calculated by convoluting with coefficients selected from Table 2 according to the subpixel offset and the filter type as follows:

$$s(x) = \left(\sum_{i=0}^{i<4} (\text{ref}_{i+x} \cdot c_i) + 32 \right) \gg 6$$

- 5 In this equation, “ $\gg$ ” indicates a bitwise shift-right operation.

Another set of interpolation filters that have 6-bit precision is presented in Table 3.

Table 3: A set of interpolation filters with 6-bit precision

Subpixel offset	Chroma DCT-IF filter				Gaussian filter

FIG. 11 illustrates a schematic diagram of a plurality of intra prediction modes used in the HEVC UIP scheme. For luminance blocks, the intra prediction modes may comprise up to 36 intra prediction modes, which may include three non-directional modes and 33 directional modes. The non-directional modes may comprise a planar prediction mode, a mean (DC) prediction mode, and a chroma from luma (LM) prediction mode. The planar prediction mode may perform predictions by assuming a block amplitude surface with a horizontal and vertical slope derived from the boundary of the block. The DC prediction mode may perform predictions by assuming a flat block surface with a value matching the mean value of the block boundary. The LM prediction mode may perform predictions by assuming a chroma value for the block matches the luma value for the block. The directional modes may perform predictions based on adjacent blocks as shown in FIG. 11.

H.264/AVC and HEVC specifies that a low-pass filter could be applied to reference samples prior to the reference samples being used in an intra prediction process. A decision on whether to use a reference sample filter or not is determined by intra prediction mode and block size. This mechanisms may be referred to as Mode Dependent Intra Smoothing (MDIS). There also exists a plurality of methods related to MDIS. For example, the Adaptive Reference Sample Smoothing (ARSS) method may explicitly (e.g. a flag is included into a bitstream) or implicitly (for example, data hiding is used to avoid putting a flag into a bitstream to reduce signaling

overhead) signal whether the prediction samples are filtered. In this case, the encoder may make the decision on smoothing by testing the Rate-Distortion (RD) cost for all potential intra prediction modes.

FIG. 10A shows an example of 67 intra prediction modes, e.g., as proposed for VVC, the plurality of intra prediction modes of 67 intra prediction modes comprising: planar mode (index 0), dc mode (index 1), and angular modes with indices 2 to 66, wherein the left bottom angular mode in Fig 10A refers to index 2 and the numbering of the indices being incremented until index 66 being the top right most angular mode of FIG. 10A.

As shown in FIG. 10B and FIG. 10C, starting from the second version VVC has some modes corresponding to skew intra prediction directions, including wide angle ones (shown as dashed lines). For any of these modes, to predict samples within a block, interpolation of a set of neighboring reference samples should be performed, if a corresponding position within a block side is fractional. HEVC and VVC uses linear interpolation between two adjacent reference samples. JEM uses more sophisticated 4-tap interpolation filters. Filter coefficients are selected to be either Gaussian or Cubic ones depending on the width or on the height value. The decision on whether to use width or height is harmonized with the decision on main reference side selection: when the intra prediction mode is greater or equal to the diagonal mode, the top side of reference samples is selected to be the main reference side and the width value is selected to determine the interpolation filter in use. Otherwise, the main side reference is selected from the left side of the block and the height controls the filter selection process. Specifically, if the selected side length is smaller than or equal to 8 samples, Cubic interpolation 4 tap is applied. Otherwise, the interpolation filter is a 4-tap Gaussian one.

In VVC, a partitioning mechanism based on both quad-tree and binary tree and known as QTBT is used. As depicted in FIG. 12, QTBT partitioning can provide not just square but rectangular blocks as well. Of course, some signaling overhead and increased computational complexity at the encoder side are the price of the QTBT partitioning as compared to conventional quad-tree based partitioning used in the HEVC/H.265 standard. Nevertheless, the QTBT-based partitioning is endowed with better segmentation properties and, hence, demonstrates significantly higher coding efficiency than the conventional quad-tree.

Leaves of the trees used for partitioning are being processed in a Z-scan order, so that the current block corresponding to the current leaf will have left and above neighbor blocks, that

are already reconstructed during encoding or decoding processes, unless the current block is located on the boundary of the slice. This is also illustrated in FIG. 12. Left-to-right scan of the leaves of the tree shown in the right part of FIG. 12 corresponds to the spatial Z-scan order of the blocks shown in the left part of this figure. The same scan is applied in case of quad-tree or multi-type trees.

For directional intra prediction, reference samples are obtained from the samples of the previously reconstructed neighboring blocks. Depending on the size of the block and the intra prediction mode, a filter could be applied to the reference samples prior to being used to obtain values of predicted samples.

- 10 In case of boundary smoothing and PDPC, several first columns or several first rows of the predicted block are combined with the additional prediction signal generated from the neighboring samples.

Particular implementation of a simplified PDPC could be performed differently, depending on the intra prediction mode:

- 15 For planar, DC, HOR/VER (horizontal/vertical) intra prediction modes (denoted as 0, 1, 18, 50 respectively in FIG.10B and FIG. 10C), the following steps are performed:

The predicted sample $\hat{P}(x, y)$ located at (x, y) is calculated as follows:

$$\hat{P}(x, y) = \text{Clip1Cmp}((wL \times R_{-1,y} + wT \times R_{x,-1} - wTL \times R_{-1,-1} + (64 - wL - wT + wTL) \times P(x, y) + 32) \gg 6) \quad (1)$$

- 20 where $R_{x,-1}$, $R_{-1,y}$ represent the reference samples located at the top and the left of the current sample (x, y) , and $R_{-1,-1}$ represents the reference sample located in the top-left corner of the current block. $P(x, y)$ denotes the value of the predicted sample when applying the planar, DC or HOR/VER intra prediction mode, as indicated above. The function clip1Cmp is set as follows:

- 25 - If cIdx, a parameter that specifies the color component of the current block, is equal to 0, clip1Cmp is set equal to Clip1Y.
- Otherwise, clip1Cmp is set equal to Clip1C

$$\text{Clip1}_Y(x) = \text{Clip3}(0, (1 \ll \text{BitDepth}_Y) - 1, x)$$

$$\text{Clip1}_C(x) = \text{Clip3}(0, (1 \ll \text{BitDepth}_C) - 1, x)$$

$$\text{Clip3}(x, y, z) = \begin{cases} x & ; \quad z < x \\ y & ; \quad z > y \\ z & ; \quad \text{otherwise} \end{cases}$$

BitDepth_Y is the bit depth of luma samples.

5 BitDepth_C is the bit depth of chroma samples.

BitDepth_Y and BitDepth_C could be signaled in sequence parameter set (SPS) of a bitstream;

Alternative definitions of $\text{Clip1}_Y(x)$ and $\text{Clip1}_C(x)$ are possible. In particular, as described by F. Galpin, P. Bordes, and F. Le Léannec in contribution JVET-C0040 “Adaptive Clipping in JEM2.0”, $\text{Clip1Cmp}(x) = \text{Clip3}(\min_C, \max_C, x)$,

10 where $\min_C$ is the lower clipping bound used in current slice for component ID C ,

$\max_C$ is the upper clipping bound used in current slice for component ID C ,

C is a color component (e.g., Y for luma, Cb and Cr for chroma),

“ $x \gg y$ ” is an arithmetic right shift of a two's complement integer representation of x by y binary digits. This function is defined only for non-negative integer values of y . Bits shifted
15 into the most significant bits (MSBs) as a result of the right shift have a value equal to the MSB of x prior to the shift operation.

The DC mode weights are calculated as follows:

$$wT = 32 \gg ((y \ll 1) \gg \text{shift}), wL = 32 \gg ((x \ll 1) \gg \text{shift}),$$

$$wTL = (wL \gg 4) + (wT \gg 4),$$

20 Where $\text{shift} = (\log_2(\text{width}) + \log_2(\text{height}) + 2) \gg 2$.

For planar mode, $wTL = 0$, while for the horizontal mode $wTL = wT$ and for vertical mode $wTL = wL$. As an example, DC mode PDPC weights (wL , wT , wTL) for (0, 0) and (1, 0) positions inside one 4x4 block are shown in FIG. 13. From this Figure it follows, that a clipping operation

as defined, for instance, in equation (1) is mandatory. However, the state-of-the-art PDPC implementation has a potential flaw, which is illustrated in the following example where the result of the clipping procedure could be out of the range determined by BitDepth_v or BitDepth_c :

5 Given $R_{-1,y} = 0$, $R_{x,-1} = 0$, $R_{-1,-1} = 100$, $P(x,y) = 0$, from equation (1) it follows that for the (0,0) position of a 4x4 predicted block $\hat{P}(x,y) = \text{Clip1Cmp}((wL \times R_{-1,y} + wT \times R_{x,-1} - wTL \times R_{-1,-1} + (64 - wL - wT + wTL) \times P(x,y) + 32)) \gg 6 = \text{Clip1Cmp}((-wTL \times R_{-1,-1} + 32) \gg 6) = \text{Clip1Cmp}((-4 \times 100 + 32) \gg 6)$, with $wTL = 4$, as shown in FIG. 13.

10 As seen from the example above, a negative value “ $-4 \times 100 + 32 = -368$ ” is being right-shifted using arithmetic bit shift. Depending on the implementation, arithmetic right bit shift of a negative value may lead to different output (e.g., in case of C/C++ programming language) and thus it could not be guaranteed that $\text{Clip1Cmp}()$ output will always be 0, since the result of shifting a negative value to the right may have a positive sign and a non-zero magnitude in specific implementations.

Although the issue related to clipping performed in PDPC is described for planar intra-prediction, a similar situation may occur for PDPC using DC intra prediction.

15 For diagonal (denoted as 2 and 66 in FIG.10B and FIG. 10C) and adjacent modes (directional modes not less than 58 or not greater than 10 in FIG. 10B or FIG. 10C) processing is performed as described below using the same formula (1):

20 FIG. 14A illustrates the definition of reference samples $R_{x,-1}$, $R_{-1,y}$ and $R_{-1,-1}$ for the extension of PDPC to the top-right diagonal mode. The prediction sample $\text{pred}(x', y')$ is located at (x', y') within the prediction block. The coordinate x of the reference sample $R_{x,-1}$ is given by: $x = x' + y' + 1$, and the coordinate y of the reference sample $R_{-1,y}$ is similarly given by: $y = x' + y' + 1$.

The PDPC weights for the top-right diagonal mode are:

$$wT = 16 \gg ((y' < 1) \gg \text{shift}), wL = 16 \gg ((x' < 1) \gg \text{shift}), wTL = 0.$$

Similarly, FIG. 14B illustrates the definition of reference samples $R_{x,-1}$, $R_{-1,y}$ and $R_{-1,-1}$ for the extension of PDPC to the bottom-left diagonal mode. The coordinate x of the reference sample $R_{x,-1}$ is given by: $x = x' + y' + 1$, and the coordinate y of the reference sample $R_{-1,y}$ is: $y = x' + y' + 1$. The PDPC weights for the bottom-left diagonal mode are: $wT = 16 \gg ((y' < 1) \gg \text{shift})$, $wL = 16 \gg ((x' < 1) \gg \text{shift})$, $wTL = 0$. The case of an adjacent top-right diagonal mode is illustrated in FIG. 14C. The PDPC weights for an adjacent top-right diagonal mode are: $wT = 32 \gg ((y' < 1) \gg \text{shift})$, $wL = 0$, $wTL = 0$. Similarly, the case of an adjacent bottom-left diagonal mode is illustrated in FIG. 14D. The PDPC weights for an adjacent bottom-left diagonal mode are: $wL = 32 \gg ((x' < 1) \gg \text{shift})$, $wT = 0$, $wTL = 0$. The reference sample coordinates for the last two cases are computed using the tables that are already used for angular mode intra prediction. Linear interpolation of the reference samples is used if fractional reference sample coordinates are calculated.

Simplified PDPC could be performed as specified in the VVC specification. Further, the following denotation are used:

$\text{invAngle} = \text{Round}\left(\frac{256 \cdot 32}{\text{intraPredAngle}}\right)$, is the value of inverse angle,

$\text{Round}(x) = \text{Sign}(x) * \text{Floor}(\text{Abs}(x) + 0.5)$,

$$\text{Sign}(x) = \begin{cases} 1 & ; \quad x > 0 \\ 0 & ; \quad x = 0 \\ -1 & ; \quad x < 0 \end{cases}$$

$\text{Floor}(x)$ is the largest integer less than or equal to x ,

$\text{Log2}(x)$ is the base-2 logarithm of x .

intraPredAngle is the angle parameter specified in Table 4,

$A = C ? B : D$ is a ternary assignment operation, where A is set equal to B if condition C is true. Otherwise, if condition C is false, A is set equal to D .

INTRA_PLANAR is a planar intra prediction mode (),

INTRA_DC is a DC intra prediction mode,

INTRA_ANGULAR XX is one of the directional intra prediction modes, where XX denotes its number and corresponding direction shown in FIG. 10B or 10C.

If a term is not explained herein, it is understood that its definition can be found in the VVC specification or HEVC/H.265 standard specification.

5 Given the denotations above, the steps of simplified PDPC could be defined as follows:

Inputs to this process are:

- the intra prediction mode predModeIntra ,
- a variable nTbW specifying the transform block width,
- a variable nTbH specifying the transform block height,
- 10 – a variable refW specifying the reference samples width,
- a variable refH specifying the reference samples height,
- the predicted samples $\text{predSamples}[x][y]$, with $x = 0..\text{nTbW} - 1$, $y = 0..\text{nTbH} - 1$,
- the neighbouring samples $p[x][y]$, with $x = -1$, $y = -1..\text{refH} - 1$ and $x = 0..\text{refW} - 1$, $y = -1$,
- 15 – a variable cIdx specifying the color component of the current block.

Outputs of this process are the modified predicted samples $\text{predSamples}[x][y]$ with $x = 0..\text{nTbW} - 1$, $y = 0..\text{nTbH} - 1$.

Depending on the value of cIdx , the function clip1Cmp is set as follows:

- If cIdx is equal to 0, clip1Cmp is set equal to Clip1_Y .
- 20 – Otherwise, clip1Cmp is set equal to Clip1_C .

The variable nScale is set to $((\text{Log2}(\text{nTbW}) + \text{Log2}(\text{nTbH}) - 2) \gg 2)$.

The reference sample arrays $\text{mainRef}[x]$ and $\text{sideRef}[y]$, with $x = 0..\text{refW} - 1$ and $y = 0..\text{refH} - 1$ are derived as follows:

$$\text{mainRef}[x] = p[x][-1]$$

$$\text{sideRef}[y] = p[-1][y]$$

The variables $\text{refL}[x][y]$, $\text{refT}[x][y]$, $\text{wT}[y]$, $\text{wL}[x]$ and $\text{wTL}[x][y]$ with $x = 0..nTbW - 1$, $y = 0..nTbH - 1$ are derived as follows:

- 5 – If predModeIntra is equal to INTRA_PLANAR, INTRA_DC, INTRA_ANGULAR18, or INTRA_ANGULAR50, the following applies:

$$\text{refL}[x][y] = p[-1][y]$$

$$\text{refT}[x][y] = p[x][-1]$$

$$\text{wT}[y] =$$

$$10 \quad 32 \gg ((y \ll 1) \gg nScale)$$

$$\text{wL}[x] =$$

$$32 \gg ((x \ll 1) \gg nScale)$$

$$\text{wTL}[x][y] = (\text{predModeIntra} == \text{INTRA_DC}) ? ((\text{wL}[x] \gg 4) + (\text{wT}[y] \gg 4)) : 0$$

- 15 – Otherwise, if predModeIntra is equal to INTRA_ANGULAR2 or INTRA_ANGULAR66, the following applies:

$$\text{refL}[x][y] = p[-1][x + y + 1]$$

$$\text{refT}[x][y] = p[x + y + 1][-1]$$

$$\text{wT}[y] = (32 \gg 1) \gg ((y \ll 1) \gg nScale)$$

$$20 \quad \text{wL}[x] = (32 \gg 1) \gg ((x \ll 1) \gg nScale)$$

$$\text{wTL}[x][y] = 0$$

- Otherwise, if predModeIntra is less than or equal to INTRA_ANGULAR10, the following ordered steps apply:

1. The variables $\text{dXPos}[y]$, $\text{dXFrac}[y]$, $\text{dXInt}[y]$ and $\text{dX}[x][y]$ are derived as follows using invAngle :

25

dXPos[y] = ((y + 1) * invAngle + 2) >> 2

dXFrac[y] = dXPos[y] &

63

dXInt[y] = dXPos[y] >> 6

5 dX[x][y] = x + dXInt[y]

2. The variables refL[x][y], refT[x][y], wT[y], wL[x] and wTL[x][y] are derived as follows:

refL[x][y] = 0

10 refT[x][y] = (dX[x][y] < refW - 1) ? ((64 -
dXFrac[y]) * mainRef[dX[x][y]] + dXFrac[y] * mainRef[dX[x][y] + 1] +
32) >> 6 : 0 (Eq. 1)

wT[y] = (dX[x][y] < refW - 1) ? 32 >> ((y << 1) >> nScale) : 0

wL[x] = 0

wTL[x][y] = 0

- 15 – Otherwise, if predModeIntra is greater than or equal to INTRA_ANGULAR58 (see FIG. 10B or 10C), the following ordered steps apply:

1. The variables dYPos[x], dYFrac[x], dYInt[x] and dY[x][y] are derived as follows using invAngle as specified in below depending on intraPredMode:

20 dYPos[x] = ((x + 1) * invAngle + 2) >> 2

dYFrac[x] = dYPos[x] &

63

dYInt[x] = dYPos[x] >> 6

dY[x][y] = y + dYInt[x]

- 25 2. The variables refL[x][y], refT[x][y], wT[y], wL[x] and wTL[x][y] are derived as follows:

$$\text{refL}[x][y] = (\text{dY}[x][y] < \text{refH} - 1) ? ((64 - \text{dYFrac}[x]) * \text{sideRef}[\text{dY}[x][y]] + \text{dYFrac}[x] * \text{sideRef}[\text{dY}[x][y] + 1] + 32) >> 6 : 0 \quad (\text{Eq. 2})$$

$$\text{refT}[x][y] = 0$$

$$5 \quad \text{wT}[y] = 0$$

$$\text{wL}[x] = (\text{dY}[x][y] < \text{refH} - 1) ? 32 >> ((x << 1) >> \text{nScale}) : 0$$

$$\text{wTL}[x][y] = 0$$

– Otherwise, $\text{refL}[x][y]$, $\text{refT}[x][y]$, $\text{wT}[y]$, $\text{wL}[x]$ and $\text{wTL}[x][y]$ are all set equal to 0.

10 The values of the modified predicted samples $\text{predSamples}[x][y]$, with $x = 0..nTbW - 1$, $y = 0..nTbH - 1$ are derived as follows:

$$\begin{aligned} \text{predSamples}[x][y] = & \text{clip1Cmp}((\text{refL}[x][y] * \text{wL}[x] + \text{refT}[x][y] * \text{wT}[y] - \\ & \text{p}[-1][-1] * \text{wTL}[x][y] + (64 - \text{wL}[x] - \text{wT}[y] + \\ & \text{wTL}[x][y]) * \text{predSamples}[x][y] + 32) >> 6) \end{aligned}$$

15

In the assignment of Eq. 1 above, the simplified PDPC may use nearest-neighbor interpolation instead of linear one:

$$\text{refT}[x][y] = (\text{dX}[x][y] < \text{refW} - 1) ? \text{mainRef}[\text{dX}[x][y]] : 0$$

20 Similarly, in the assignment of Eq. 2 above, the simplified PDPC could also use nearest-neighbor interpolation:

$$\text{refL}[x][y] = (\text{dY}[x][y] < \text{refH} - 1) ? \text{sideRef}[\text{dY}[x][y]] : 0$$

Thus, at both encoder and decoder sides, the method uses the following as the input data:

directional intra prediction mode (denoted further as predModeIntra , which is shown in FIG. 10B and FIG. 10C)

block size parameter $nTbS$, which is set equal to $(\log_2(nTbW) + \log_2(nTbH)) \gg 1$, where $nTbW$ and $nTbH$ denote width and height of the predicted block, respectively, and “ $\gg$ ” denotes a right-shift operation.

5 The modification of the VVC specification that enables usage of the method may comprise substituting “the neighbouring samples $p[x][y]$ ” by “the reference samples $p[x][y]$ ” in the section describing simplified PDPC.

The angle parameter $intraPredAngle$ denotes the subpixel offset between two adjacent rows of predicted samples in fixed point representation having a length of fractional part equal to 5-bits. This parameter ($intraPredAngle$) could be derived from the intra prediction mode ($predModeIntra$). An exemplary derivation of $intraPredAngle$ from $predModeIntra$ could be
 10 defined with a look-up-table (LUT), e.g., as it is shown in Table 4.

Table 4. An exemplary LUT to derive intraPredAngle from predModelIntra.

predModelIntra														-14	-13	-12	-11
intraPredAngle														512	341	256	171
predModelIntra	-10	-9	-8	-7	-6	-5	-4	-3	-2	-1	2	3	4	5	6	7	8

From the current HEVC and VVC draft specification, a planar intra prediction method is used.

The part of the VVC draft 3 is incorporated below for reference:

5 8.2.4.2.5. Specification of INTRA_PLANAR intra prediction mode

Inputs to this process are:

- a variable nTbW specifying the transform block width,
- a variable nTbH specifying the transform block height,
- the neighbouring samples $p[x][y]$, with $x = -1, y = -1..nTbH$ and $x = 0..nTbW, y = -1$.

10 Outputs of this process are the predicted samples $predSamples[x][y]$, with $x = 0..nTbW - 1$,
 $y = 0..nTbH - 1$.

The values of the prediction samples $\text{predSamples}[x][y]$, with $x = 0..nTbW - 1$ and $y = 0..nTbH - 1$, are derived as follows:

$$\text{predV}[x][y] = ((nTbH - 1 - y) * p[x][-1] + (y + 1) * p[-1][nTbH]) \ll \text{Log2}(nTbW) \quad (8-82)$$

$$\text{predH}[x][y] = ((nTbW - 1 - x) * p[-1][y] + (x + 1) * p[nTbW][-1]) \ll \text{Log2}(nTbH) \quad (8-83)$$

$$\begin{aligned} \text{predSamples}[x][y] &= (\text{predV}[x][y] + \text{predH}[x][y] + nTbW * nTbH) \gg \\ &(\text{Log2}(nTbW) + \text{Log2}(nTbH) + 1) \end{aligned} \quad (8-84)$$

The present disclosure addresses the problem described above related to a shift operation of a negative value when applying DC intra prediction using PDPC, which may result in an erroneous predicted sample value.

The provided solution involves an alternative PDPC method that does not have the flaw of equation (1).

Specifically, the method comprises the following steps, as illustrated in the flowchart of FIG. 15. The illustrated method of intra-predicting a block of a picture is performed for each sample from a plurality of samples of the block.

In step S100, a predicted sample value from one or more reference sample values is obtained by intra-prediction using a DC intra-prediction mode.

Further, in step S110, the predicted sample value is multiplied with a sample weighting factor, resulting in a weighted predicted sample value. In particular, the sample weighting factor is calculated as $((2 \ll p) - wL - wT)$, wherein p is a precision of the sample weighting factor, wL is a horizontal weighting factor, and wT is a vertical weighting factor.

In step S120, an additional value is added to the weighted predicted sample value, resulting in a non-normalized predicted sample value.

In step S130, the non-normalized predicted sample value is normalized by an arithmetic right-shift of an integer representation of the non-normalized predicted sample value.

Hence, by the illustrated method, normalized predicted sample values may be determined applying DC intra-prediction in the framework of PDPC while preventing occurrence of

erroneous prediction values by performing a determination method not necessarily requiring a clipping procedure.

Note that preceding to the illustrated method steps as well as following the illustrated method steps, further processing may be applied.

- 5 For instance, residual values may be added to the normalized predicted sample values, resulting in reconstructed sample values.

In an embodiment, the additional value may include a rounding offset. An arithmetic right shift operation, which corresponds to a division by a power of two, typically results in a rounded off value. In order to ensure a properly rounded result, a rounding offset may be added prior to
10 performing the right shift operation. The rounding offset value corresponds to half of an integer value after performing the right shift operation. Thus, adding the rounding offset ensures a properly rounded resulting value. For instance, in a case of a right shift by 6 bits, which corresponds to a division by $2^6=64$, the rounding offset would be 32.

In another embodiment, a method of intra predicting a first block and a second block of a picture is provided. For each sample from a plurality of samples of the first block as well as for
15 each sample from a plurality of samples of the second block, the steps illustrated in FIG. 15 and described above steps are performed, with the difference that the intra-prediction mode used for obtaining the predicted sample values for the first block is a DC intra-prediction mode, and the intra-prediction mode used for obtaining the predicted sample values for the second
20 block is a planar intra-prediction mode.

Specifically, for each sample of the first block, in step S100, a predicted sample value is obtained from one or more reference sample values by intra-prediction using a DC intra prediction mode. Further, for each sample of the second block, in step S100, a predicted sample value is obtained from one or more reference sample values by intra-prediction using a
25 PLANAR intra prediction mode

In an embodiment, the described methods may be included in a method of encoding or decoding a picture. Specifically, predicted sample values may be obtained by performing the steps of any one of above methods. Further, by adding residual values to the obtained normalized predicted sample values, reconstructed sample values may be obtained.

Embodiments of the present disclosure may allow for a technical benefit in hardware design simplification and a reduced number of conditional checks to be performed. The steps performed to obtain predicted sample values for Planar and DC intra prediction modes are different from the steps of directional intra prediction. An exemplary hardware implementation of intra prediction would contain at least two modules:

- directional intra prediction module,
- non-directional intra prediction module.

Due to this reason, it is desirable to harmonize, first of all, PDPC filtering within each of these groups. Taking into account the fact that the complexity of PDPC for DC mode exceeds the complexity of PDPC for planar mode, the present disclosure allows for simplifying PDPC processing for the DC mode.

The two modules would implement their own PDPC filtering processing in accordance with the embodiments of the invention. The prior-art solutions required either to perform an additional check whether the intra prediction mode is DC or planar in the PDPC filtering in the non-directional intra prediction module or to implement separate PDPC filtering modules for DC and planar intra prediction modes, which causes increased hardware complexity and energy consumption. Hence, harmonizing PDPC for both DC and planar modes may allow for sharing PDPC processing (in the case of hardware, a corresponding module) for DC and planar intra prediction modes.

Another technical benefit of embodiments according to the present disclosure is revealed when being used in intra prediction design of simplified encoders. DC intra prediction mode is typically the most computationally simple intra prediction mode, thus, in a worst-case scenario, complexity of PDPC filtering may exceed the complexity of the DC mode itself. By reducing the number of conditional checks and/or the quantity of operations for the DC mode, according to the present disclosure, the overall complexity of intra prediction may be reduced, especially in the scenarios of simplified encoding that is implemented in so called “lazy” encoders, which operate with a constrained set of intra prediction modes.

The proposed method may be implemented by defining within the non-directional intra prediction method that PDPC processing is the same for both intra prediction modes processed by said module. In other words, an embodiment of the present disclosure could be realized by

introducing changes to a non-directional intra prediction module only in a way that PDPC processing is the same for DC and planar intra prediction modes.

The weighting factors wL and wT may be each a power of two, which may allow for implementation of a multiplication therewith using a shift operator. This definition is hardware friendly and may allow for improved processing efficiency. Thus, harmonizing the PDPC processing when using the DC intra prediction mode with the PDPC processing when using the planar intra prediction mode may simplify intra prediction using PDPC, for instance. The methods described above may be performed by a predictor device, an encoder device or a decoder device as illustrated in Fig. 16A, for instance.

The predictor, encoder or decoder device 1000 comprises an obtainer 1010, a multiplier 1020, an adder 1030, and a normalizer 1040. The obtainer 1010 is configured to obtain a predicted sample value from one or more reference sample values by intra-prediction using a DC intra-prediction mode. The multiplier 1020 is configured to multiply the predicted sample value by a sample weighting factor, resulting in a weighted predicted sample value. In particular, the weighting factor is $((2 \ll p) - wL - wT)$, wherein p is a parameter (a precision, for example) of the sample weighting factor, wL is a horizontal weighting factor, and wT is a vertical weighting factor. The adder 1030 is configured to add an additional value to the weighted predicted sample value, resulting in a non-normalized predicted sample value, and the normalizer 1040 is configured to normalize the non-normalized predicted sample value by an arithmetic right shift of an integer representation of the non-normalized predicted sample value.

Similarly, in an embodiment, the obtainer 1010 of the predictor, encoder or decoder device 1000 may be configured to obtain, for each sample of a plurality of samples of a first block and for each sample from a plurality of samples of a second block a predicted sample value from one or more reference sample values by intra-prediction using a intra-prediction mode. The intra prediction mode used for obtaining the predicted values of the sample may be a DC intra prediction mode for the first block and a planar intra prediction mode for the second block. The multiplier 1020 is configured to multiply the predicted sample value by a sample weighting factor, resulting in a weighted predicted sample value. In particular, the weighting factor is $((2 \ll p) - wL - wT)$, wherein p is a parameter (a precision, for example) of the sample weighting factor, wL is a horizontal weighting factor, and wT is a vertical weighting factor. The adder 1030 is configured to add an additional value to the weighted predicted sample value, resulting in a non-normalized predicted sample value, and the normalizer 1040 is configured to

normalize the non-normalized predicted sample value by an arithmetic right shift of an integer representation of the non-normalized predicted sample value.

The predictor, encoder or decoder device 1000 may, in an embodiment, further add a residual value to the normalized predicted sample values, resulting in reconstructed sample values.

- 5 In an embodiment of the described method, the horizontal weighting factor wL may be a factor, which is applied to a value of a left reference sample resulting in a weighted left reference sample value. Further, the vertical weighting factor wT may be a factor, which is applied to a value of a top reference sample resulting in a weighted top reference sample value.

- 10 Specifically, for example, the weighted left and top reference sample values may be obtained by multiplication of the left and top reference sample values, respectively, with corresponding horizontal and vertical weighting factors wL and wT .

Further, in an embodiment, the additional value may be obtained including a summation of the weighted top reference sample value and the weighted left reference sample values.

- 15 The functional components of the encoder or decoder device 1000 may be implemented by processing circuitry 1040 configured to perform any one of the above methods, as illustrated in FIG 16B.

In an embodiment, the processing circuitry may comprise one or more processors 1050 and a non-transitory computer-readable storage medium 1060, which is connected to the one or more processors 1050. The storage medium includes program code, which, when executed by a processor, causes the processor to perform any one of the above methods.

In a specific embodiment, the method may comprise the following step:

- 20 The normalized predicted sample $\hat{P}(x, y)$ located at (x, y) may be calculated as follows:

$$\hat{P}(x, y) = (wL \times R_{-1,y} + wT \times R_{x,-1} + (64 - wL - wT) \times P(x, y) + 32) \gg 6 \quad (2)$$

where $R_{x,-1}$, $R_{-1,y}$ represents the reference samples located above (top) and to the left of the current sample (x, y) , respectively. $P(x, y)$ denotes the value of the predicted sample, which is predicted using a DC intra prediction mode.

- 25 In the above formula, the weighted predicted sample is represented by $(64 - wL - wT) \times P(x, y)$ and the additional value is represented by $wL \times R_{-1,y} + wT \times R_{x,-1} + 32$. The normalization is represented by the bitwise right-shift

operation $\gg 6$. However, the present disclosure is not limited to the specific definition of the additional value, the shift operation by 6 bits.

It is worth noting that the function clip1Cmp is not in use in an embodiment using equation (2) since the values of the predicted sample $P(x, y)$ are always in the range of valid values, i.e. between minimum and maximum of pixel values. However, the present disclosure is not limited to not performing a clipping operation and clipping may still be applied.

For instance, a normalized predicted sample value may be computed from the predicted sample value, including calculating

$$(wL \times R_{-1,y} + wT \times R_{x,-1} + (64 - wL - wT) \times P(x, y) + 32) \gg 6$$

In this implementation form, the normalization is realized by the right shift operator $\gg 6$. The present disclosure is not limited to the specific computation given above, and a mathematical equivalent calculation may be performed.

Thus, the issue of negative values leading to the occurrence of erroneous positive non-zero predicted sample values by use of said clipping operation may be prevented by applying above-mentioned calculation of the predicted sample value.

In above formulas, “ $x \gg y$ ” is an arithmetic right shift of a two's complement integer representation of x by y binary digits. This function is defined only for non-negative integer values of y . Bits shifted into the most significant bits (MSBs) as a result of the right shift have a value equal to the MSB of x prior to the shift operation.

The DC mode weights may be calculated as follows:

$$wT = 32 \gg ((y \ll 1) \gg shift), wL = 32 \gg ((x \ll 1) \gg shift),$$

where $shift = (\log_2(width) + \log_2(height) + 2) \gg 2$.

As an example, DC mode PDPC weights (wL , wT) for (0, 0) and (1, 0) positions inside one 4x4 block are shown in FIG. 17. In this example, the values of the weight wL and wT is 32 for the predicted sample at coordinates (0,0). Further, in the example, the values of the weight wL is 8 and the value of the weights wT is 32 for the predicted sample at coordinates (1,0). It could be noticed, that in comparison to the weights for predicted samples at coordinates (0,0) and (1,0) illustrated in FIG. 13, the top-left reference sample is not used and a weight for this sample

(top-left reference sample) is not specified. However, the present disclosure is not limited to the described DC mode PDPC weight calculation procedure and said DC mode PDPC weights may be determined in a different way or by applying a different formula.

The provided method could be represented in the form of a part of VVC specification:

5 Position-dependent intra prediction sample filtering process

Inputs to this process are:

- the intra prediction mode `predModeIntra`,
- a variable `nTbW` specifying the transform block width,
- a variable `nTbH` specifying the transform block height,
- 10 – a variable `refW` specifying the reference samples width,
- a variable `refH` specifying the reference samples height,
- the predicted samples `predSamples[ x ][ y ]`, with $x = 0..nTbW - 1$, $y = 0..nTbH - 1$,
- the neighbouring samples `p[ x ][ y ]`, with $x = -1$, $y = -1..refH - 1$ and $x = 0..refW - 1$, $y = -1$,
- 15 – a variable `cIdx` specifying the color component of the current block.

Outputs of this process are the modified predicted samples `predSamples[ x ][ y ]` with $x = 0..nTbW - 1$, $y = 0..nTbH - 1$.

Depending on the value of `cIdx`, the function `clip1Cmp` is set as follows:

- If `cIdx` is equal to 0, `clip1Cmp` is set equal to `Clip1Y`.
- 20 – Otherwise, `clip1Cmp` is set equal to `Clip1C`.

The variable `nScale` is set to $((\text{Log2}(nTbW) + \text{Log2}(nTbH) - 2) \gg 2)$.

The reference sample arrays `mainRef[ x ]` and `sideRef[ y ]`, with $x = 0..refW - 1$ and $y = 0..refH - 1$ are derived as follows:

$$\text{mainRef}[x] = p[x][-1]$$

$$\text{sideRef}[y] = p[-1][y]$$

The variables $\text{refL}[x][y]$, $\text{refT}[x][y]$, $wT[y]$ and $wL[x]$ with $x = 0..nTbW - 1$, $y = 0..nTbH - 1$ are derived as follows:

- 5 – If predModeIntra is equal to INTRA_PLANAR , INTRA_DC , INTRA_ANGULAR18 , or INTRA_ANGULAR50 , the following applies:

$$\text{refL}[x][y] = p[-1][y]$$

$$\text{refT}[x][y] = p[x][-1]$$

$$wT[y] = 32 \gg ((y \ll 1) \gg nScale)$$

10 $wL[x] = 32 \gg ((x \ll 1) \gg nScale)$

- Otherwise, if predModeIntra is equal to INTRA_ANGULAR2 or INTRA_ANGULAR66 , the following applies:

$$\text{refL}[x][y] = p[-1][x + y + 1]$$

$$\text{refT}[x][y] = p[x + y + 1][-1]$$

15 $wT[y] = (32 \gg 1) \gg ((y \ll 1) \gg nScale)$

$$wL[x] = (32 \gg 1) \gg ((x \ll 1) \gg nScale)$$

- Otherwise, if predModeIntra is less than or equal to INTRA_ANGULAR10 , the following ordered steps apply:

- 20 1. The variables $dXPos[y]$, $dXFrac[y]$, $dXInt[y]$ and $dX[x][y]$ are derived as follows using invAngle as specified in clause 8.2.4.2.7 depending on intraPredMode :

$$dXPos[y] = ((y + 1) * \text{invAngle} + 2) \gg 2$$

$$dXFrac[y] = dXPos[y] \& 63$$

$$dXInt[y] = dXPos[y] \gg 6$$

$$dX[x][y] = x + dXInt[y]$$

- 25 2. The variables $\text{refL}[x][y]$, $\text{refT}[x][y]$, $wT[y]$, $wL[x]$ are derived as follows:

$$\text{refL}[x][y] = 0$$

$$\text{refT}[x][y] = (\text{dX}[x][y] < \text{refW} - 1) ? ((64 - \text{dXFrac}[y]) * \text{mainRef}[\text{dX}[x][y]] + \text{dXFrac}[y] * \text{mainRef}[\text{dX}[x][y] + 1] + 32) >> 6 : 0$$

$$\text{wT}[y] = (\text{dX}[x][y] < \text{refW} - 1) ? 32 >> ((y < 1) >> \text{nScale}) : 0$$

$$\text{wL}[x] = 0$$

- 5 – Otherwise, if `predModeIntra` is greater than or equal to `INTRA_ANGULAR58`, the following ordered steps apply:

1. The variables `dYPos[x]`, `dYFrac[x]`, `dYInt[x]` and `dY[x][y]` are derived as follows using `invAngle` as specified in clause 8.2.4.2.7 depending on `intraPredMode`:

10
$$\begin{aligned} \text{dYPos}[x] &= ((x + 1) * \text{invAngle} + 2) >> 2 \\ \text{dYFrac}[x] &= \text{dYPos}[x] \& 63 \\ \text{dYInt}[x] &= \text{dYPos}[x] >> 6 \\ \text{dY}[x][y] &= y + \text{dYInt}[x] \end{aligned}$$

2. The variables `refL[x][y]`, `refT[x][y]`, `wT[y]` and `wL[x]` are derived as follows:

15
$$\text{refL}[x][y] = (\text{dY}[x][y] < \text{refH} - 1) ? ((64 - \text{dYFrac}[x]) * \text{sideRef}[\text{dY}[x][y]] + \text{dYFrac}[x] * \text{sideRef}[\text{dY}[x][y] + 1] + 32) >> 6 : 0$$

$$\text{refT}[x][y] = 0$$

$$\text{wT}[y] = 0$$

$$\text{wL}[x] = (\text{dY}[x][y] < \text{refH} - 1) ? 32 >> ((x < 1) >> \text{nScale}) : 0$$

- 20 – Otherwise, `refL[x][y]`, `refT[x][y]`, `wT[y]`, `wL[x]` are all set equal to 0. The values of the modified predicted samples `predSamples[x][y]`, with $x = 0..nTbW - 1, y = 0..nTbH - 1$ are derived as follows:

$$\text{predSamples}[x][y] = (\text{refL}[x][y] * \text{wL}[x] + \text{refT}[x][y] * \text{wT}[y] +$$

$$(64 - \text{wL}[x] - \text{wT}[y]) * \text{predSamples}[x][y] + 32) >> 6)$$

Here “ $(64 - \text{wL}[x] - \text{wT}[y])$ ” stands for sample weighting factor.

FIG. 18 illustrates the above-described method. By the dashed line the step of clipping is shown, that is performed in the state-of-the-art PDPC, but is not necessarily performed in the proposed method, since it is not required, because the coefficient wTL is not used.

Input to the illustrated method are the reference sample values, which are indicated in the figure as $ref[]$. Using said reference sample, an intra-prediction for a current sample is performed. In particular, the intra-prediction of the current sample value may be performed using a DC intra-prediction mode. Further, additional values are calculated using the left and top reference sample values $refL[x][y]$ and $refT[x][y]$, respectively, together with the corresponding left weight $wL[x]$ and $wT[y]$. The intra-predicted sample value is multiplied by a weighting factor $(64-wL[x]-wT[y])$. Subsequently, the additional values are added to the weighted predicted sample value. Next, as the weighted predicted sample value, to which the additional values have been added does not necessarily represent a normalized value, a normalization procedure is performed by applying a bitwise right shift operation indicated with “>>” in the figure. The resulting normalized predicted sample value does not require a further clipping operation (in the figure, the superfluous clipping operation is indicated with dashed lines).

Although in the illustrated example the weighting factor is $(64-wL[x]-wT[x])$, the present disclosure is not limited thereto. In particular, the sample weighting factor may exhibit a different precision. In other words, the sample weighting factor may be expressed as $((2^{p-1}-wL-wT))$, with p being its precision. Further, although not required, a clipping process may still be performed.

In FIG. 14 reference samples are used by the intra prediction process to produce predicted samples. Each predicted sample is further weighted using a sample weighting factor. The sample weighting factor may, for example, be equal to $(64 - wL[x] - wT[y])$. The same reference samples are used to calculate additional values for each of the predicted samples depending on x and y , where x and y define the position of a predicted sample within a predicted block. These additional values are added to corresponding weighted predicted samples. Each sample resulting from this operation is then normalized by right-shifting it according to the predetermined precision of the sample weighting factor. For example, if the sample weighting factor is defined as $(64 - wL[x] - wT[y])$ the precision is 6 bits. Therefore at this step a right-shift by 6 is performed in order to ensure that possible minimum and maximum values of the output values are the same as the possible minimum and maximum values of the reference

samples. However, the present disclosure is not limited to a precision of 6 bits, and any other precision may be applied.

One of the beneficial effects of the proposed solution is that the PLANAR intra prediction mechanism can be reused to calculate the additional values. Specifically, PLANAR intra prediction may use the following equation to derive horizontal and vertical predicted sample values:

$$\begin{aligned} \text{predV}[x][y] = & ((nTbH - 1 - y) * p[x][-1] + \\ & + (y + 1) * p[-1][nTbH]) \ll \text{Log2}(nTbW) \end{aligned} \quad (8-82)$$

$$\begin{aligned} \text{predH}[x][y] = & ((nTbW - 1 - x) * p[-1][y] + \\ & + (x + 1) * p[nTbW][-1]) \ll \text{Log2}(nTbH) \end{aligned} \quad (8-83)$$

From the two above equations (8-82) and (8-83) it can be seen that $\text{predV}[x][y]$ uses reference sample $p[x][-1]$ located in the same column as $\text{predV}[x][y]$ and $\text{predH}[x][y]$ uses the reference sample $p[-1][y]$ located on the same row as $\text{predH}[x][y]$. Besides, left-shift operations are performed as the final step and thus can be skipped since they do not affect intermediate calculations that are being reused.

In the formulas (8-82) and (8-83) above, predV denotes the vertical predicted sample value determined by applying planar intra prediction and predH denotes the horizontal predicted sample value determined by applying planar intra prediction. Further, $nTbW$ and $nTbH$ denote the width and the height of the current block, respectively, when performing PLANAR intra prediction. However, $nTbW$, $nTbH$, x and y variables are inputs of PLANAR intra prediction method and thus could be adjusted correspondingly. Because of that it is possible to substitute $(nTbW - 1 - x)$ by D_x and $(nTbH - 1 - y)$ by D_y input variables. Bottom-left and top-right reference samples could be set to 0 since these are a parameters not being used.

Considering the above-described observations, the equations (8-82) and (8-83) above may be rewritten in accordance with its inputs being predetermined:

$$V_y = D_y * p[x][-1]$$

$$V_x = D_x * p[-1][y]$$

Thus, the following unifications for determining an additional value to be added to the weighted predicted sample value could be performed:

- an additional value in case of horizontal mode (mode 18) could be calculated as $V_y = D_y * p[x][y - 1]$, wherein D_y is set equal to $wT[y]$;
- 5 - an additional value in case of vertical mode (mode 50) could be calculated as $V_x = D_x * p[x - 1][y]$, wherein D_x is set equal to $wL[x]$;
- an additional value in case of DC mode (mode 1) could be calculated as $V_y + V_x$, wherein D_x and D_y are set as in the previous two cases, i.e. D_y is set equal to $wT[y]$ and D_x is set equal to $wL[x]$.
- 10 By alternation of reference sample selection it could be shown that unification could be performed for all the intra prediction modes that are specified for a PDPC process.

In another embodiment, the PDPC process may be specified as follows:

Position-dependent intra prediction sample filtering process

Inputs to this process are:

- 15 - the intra prediction mode $predModelIntra$,
- a variable $nTbW$ specifying the transform block width,
- a variable $nTbH$ specifying the transform block height,
- a variable $refW$ specifying the reference samples width,
- a variable $refH$ specifying the reference samples height,
- 20 - the predicted samples $predSamples[x][y]$, with $x = 0..nTbW - 1$, $y = 0..nTbH - 1$,
- the neighbouring samples $p[x][y]$, with $x = -1$, $y = -1..refH - 1$ and $x = 0..refW - 1$, $y = -1$.

Outputs of this process are the modified predicted samples $predSamples[x][y]$ with $x = 0..nTbW - 1$, $y = 0..nTbH - 1$.

The variable nScale is derived as follows:

- If predModelIntra is greater than INTRA_ANGULAR50, nScale is set equal to $\text{Min}(2, \text{Log2}(\text{nTbH}) - \text{Floor}(\text{Log2}(3 * \text{invAngle} - 2)) + 8)$, using invAngle as specified in clause 8.4.5.2.12.
- 5 – Otherwise, if predModelIntra is less than INTRA_ANGULAR18, not equal to INTRA_PLANAR and not equal to INTRA_DC, nScale is set equal to $\text{Min}(2, \text{Log2}(\text{nTbW}) - \text{Floor}(\text{Log2}(3 * \text{invAngle} - 2)) + 8)$, using invAngle as specified in clause 8.4.5.2.12.
- Otherwise, nScale is set to $((\text{Log2}(\text{nTbW}) + \text{Log2}(\text{nTbH}) - 2) \gg 2)$.
- 10 The reference sample arrays mainRef[x] and sideRef[y], with $x = 0..\text{refW} - 1$ and $y = 0..\text{refH} - 1$ are derived as follows:

$$\begin{aligned} \text{mainRef}[x] &= p[x][-1] \\ \text{sideRef}[y] &= p[-1][y] \end{aligned} \quad (8-229)$$

The variables refL[x][y], refT[x][y], wT[y], and wL[x] with

- 15 $x = 0..\text{nTbW} - 1, y = 0..\text{nTbH} - 1$ are derived as follows:

- If predModelIntra is equal to INTRA_PLANAR or INTRA_DC, the following applies:

$$\text{refL}[x][y] = p[-1][y] \quad (8-230)$$

$$\text{refT}[x][y] = p[x][-1] \quad (8-231)$$

$$\text{wT}[y] = 32 \gg ((y \ll 1) \gg \text{nScale}) \quad (8-232)$$

20 $\text{wL}[x] = 32 \gg ((x \ll 1) \gg \text{nScale}) \quad (8-233)$

- Otherwise, if predModelIntra is equal to INTRA_ANGULAR18 or INTRA_ANGULAR50, the following applies:

$$\text{refL}[x][y] = p[-1][y] - p[-1][-1] + \text{predSamples}[x][y] \quad (8-234)$$

$$\text{refT}[x][y] = p[x][-1] - p[-1][-1] + \text{predSamples}[x][y] \quad (8-235)$$

25 $\text{wT}[y] = (\text{predModelIntra} == \text{INTRA_ANGULAR18}) ?$
 $32 \gg ((y \ll 1) \gg \text{nScale}) : 0 \quad (8-236)$

$wL[x] = (\text{predModelIntra} == \text{INTRA_ANGULAR50}) ?$
 $32 \gg ((x \ll 1) \gg nScale) : 0$ (8-237)

- Otherwise, if predModelIntra is less than INTRA_ANGULAR18 and $nScale$ is equal to or greater than 0, the following ordered steps apply:

- 5 3. The variables $dXInt[y]$ and $dX[x][y]$ are derived as follows using $invAngle$ as specified in clause 8.4.5.2.12 depending on intraPredMode :

$dXInt[y] = ((y + 1) * invAngle + 256) \gg 9$ (8-238)
 $dX[x][y] = x + dXInt[y]$

4. The variables $refL[x][y]$, $refT[x][y]$, $wT[y]$, and $wL[x]$ are derived as follows:

10 $refL[x][y] = 0$ (8-239)

$refT[x][y] = (y < (3 \ll nScale)) ? \text{mainRef}[dX[x][y]] : 0$ (8-240)

$wT[y] = 32 \gg ((y \ll 1) \gg nScale)$ (8-241)

$wL[x] = 0$ (8-242)

- Otherwise, if predModelIntra is greater than INTRA_ANGULAR50 and $nScale$ is equal to or greater than 0, the following ordered steps apply:

15

3. The variables $dYInt[x]$ and $dY[x][y]$ are derived as follows using $invAngle$ as specified in clause 8.4.5.2.12 depending on intraPredMode :

$dYInt[x] = ((x + 1) * invAngle + 256) \gg 9$ (8-243)
 $dY[x][y] = y + dYInt[x]$

20

4. The variables $refL[x][y]$, $refT[x][y]$, $wT[y]$, and $wL[x]$ are derived as follows:

$refL[x][y] = (x < (3 \ll nScale)) ? \text{sideRef}[dY[x][y]] : 0$ (8-244)

$refT[x][y] = 0$ (8-245)

$wT[y] = 0$ (8-246)

$wL[x] = 32 \gg ((x \ll 1) \gg nScale)$ (8-247)

– Otherwise, $\text{refL}[x][y]$, $\text{refT}[x][y]$, $wT[y]$, and $wL[x]$ are all set equal to 0.

The values of the modified predicted samples $\text{predSamples}[x][y]$, with

$x = 0..nTbW - 1$, $y = 0..nTbH - 1$ are derived as follows:

$$\begin{aligned} \text{predSamples}[x][y] = & \text{Clip1}((\text{refL}[x][y] * wL[x] + \text{refT}[x][y] * wT[y] + (8-248) \\ 5 \quad & (64 - wL[x] - wT[y]) * \text{predSamples}[x][y] + 32) \gg 6) \end{aligned}$$

In the above, the function Clip1 may be defined as described further above (Clip1Cmp), for instance.

Although embodiments of the disclosure have been primarily described based on video coding, it should be noted that embodiments of the coding system 10, encoder 20 and decoder 30 (and correspondingly the system 10) and the other embodiments described herein may also be configured for still picture processing or coding, i.e. the processing or coding of an individual picture independent of any preceding or consecutive picture as in video coding. In general only inter-prediction units 244 (encoder) and 344 (decoder) may not be available in case the picture processing coding is limited to a single picture 17. All other functionalities (also referred to as tools or technologies) of the video encoder 20 and video decoder 30 may equally be used for still picture processing, e.g., residual calculation 204/304, transform 206, quantization 208, inverse quantization 210/310, (inverse) transform 212/312, partitioning 262/362, intra-prediction 254/354, and/or loop filtering 220, 320, and entropy coding 270 and entropy decoding 304.

Embodiments, e.g., of the encoder 20 and the decoder 30, and functions described herein, e.g., with reference to the encoder 20 and the decoder 30, may be implemented in hardware, software, firmware, or any combination thereof. If implemented in software, the functions may be stored on a computer-readable medium or transmitted over communication media as one or more instructions or code and executed by a hardware-based processing unit. Computer-readable media may include computer-readable storage media, which corresponds to a tangible medium such as data storage media, or communication media including any medium that facilitates transfer of a computer program from one place to another, e.g., according to a communication protocol. In this manner, computer-readable media generally may correspond to (1) tangible computer-readable storage media which is non-transitory or (2) a communication medium such as a signal or carrier wave. Data storage media may be any available media that can be accessed by one or more computers or one or more processors to

retrieve instructions, code and/or data structures for implementation of the techniques described in this disclosure. A computer program product may include a computer-readable medium.

By way of example, and not limiting, such computer-readable storage media can comprise
5 RAM, ROM, EEPROM, CD-ROM or other optical disk storage, magnetic disk storage, or other magnetic storage devices, flash memory, or any other medium that can be used to store desired program code in the form of instructions or data structures and that can be accessed by a computer. Also, any connection is properly termed a computer-readable medium. For example, if instructions are transmitted from a website, server, or other remote source using a coaxial
10 cable, fiber optic cable, twisted pair, digital subscriber line (DSL), or wireless technologies such as infrared, radio, and microwave, then the coaxial cable, fiber optic cable, twisted pair, DSL, or wireless technologies such as infrared, radio, and microwave are included in the definition of medium. It should be understood, however, that computer-readable storage media and data storage media do not include connections, carrier waves, signals, or other transitory
15 media, but are instead directed to non-transitory, tangible storage media. Disk and disc, as used herein, includes compact disc (CD), laser disc, optical disc, digital versatile disc (DVD), floppy disk and Blu-ray disc, where disks usually reproduce data magnetically, while discs reproduce data optically with lasers. Combinations of the above should also be included within the scope of computer-readable media.

20 Instructions may be executed by one or more processors, such as one or more digital signal processors (DSPs), general purpose microprocessors, application specific integrated circuits (ASICs), field programmable logic arrays (FPGAs), or other equivalent integrated or discrete logic circuitry. Accordingly, the term "processor," as used herein may refer to any of the foregoing structure or any other structure suitable for implementation of the techniques
25 described herein. In addition, in some aspects, the functionality described herein may be provided within dedicated hardware and/or software modules configured for encoding and decoding, or incorporated in a combined codec. Also, the techniques could be fully implemented in one or more circuits or logic elements. The processing circuitry mentioned in this disclosure may comprise hardware and software.

30 The techniques of this disclosure may be implemented in a wide variety of devices or apparatuses, including a wireless handset, an integrated circuit (IC) or a set of ICs (e.g., a chip set). Various components, modules, or units are described in this disclosure to emphasize

functional aspects of devices configured to perform the disclosed techniques, but do not necessarily require realization by different hardware units. Rather, as described above, various units may be combined in a codec hardware unit or provided by a collection of interoperative hardware units, including one or more processors as described above, in conjunction with
5 suitable software and/or firmware.

Further embodiments are summarized in the following.

Provided is a method of intra predicting a block of a picture, comprising for each sample from a plurality of samples of the block: obtaining a predicted sample value from one or more reference sample values by intra-prediction using one of a DC intra-prediction mode, a PLANAR intra
10 prediction mode, and an angular intra-prediction mode; multiplying the predicted sample value by a sample weighting factor, resulting in a weighted predicted sample value; adding an additional value to the weighted predicted sample value, resulting in a non-normalized predicted sample value; and normalizing the non-normalized predicted sample value by an arithmetic right shift of an integer representation of the non-normalized predicted sample value,
15 resulting in a normalized predicted sample value.

In an embodiment, the picture is part of a video sequence.

In an embodiment, the sample weighting factor is $((2^{<<p}) - wL - wT)$, wherein

p is a precision of the sample weighting factor,

wL is a horizontal weighting factor, and

wT is a vertical weighting factor.
20

In an embodiment, the horizontal weighting factor is $wL = (2^{<<(p-1)}) \gg ((x \ll 1) \gg nScale)$, wherein x is a horizontal coordinate of the sample, the vertical weighting factor is $wT = (2^{<<(p-1)}) \gg ((y \ll 1) \gg nScale)$, wherein y is a vertical coordinate of the sample, and $nScale$ is a scale parameter.

25 In an embodiment, the scale parameter $nScale$ is derived from a size of the block.

In an embodiment, the scale parameter $nScale$ is determined as $((\text{Log2}(nTbW) + \text{Log2}(nTbH) - 2) \gg 2)$ where $nTbW$ is a width of the block and $nTbH$ is a height of the block.

In an embodiment, the normalized predicted sample value is computed from the predicted sample value as

$$\hat{P}(x, y) = (wL \times R_{-1,y} + wT \times R_{x,-1} + (64 - wL - wT) \times P(x, y) + 32) \gg 6$$

where

5 $\hat{P}(x, y)$ is the normalized predicted sample value,

$P(x, y)$ is the predicted sample value,

$R_{x,-1}, R_{-1,y}$ represent the values of the nearest reference samples located above and to the left of the predicted sample,

wL is a horizontal weighting factor, and

10 wT is a vertical weighting factor.

In an embodiment, the horizontal weighting factor is $wL = (2^{((p-1))} \gg ((x \ll 1) \gg nScale))$, wherein x is a horizontal coordinate of the sample, the vertical weighting factor is $wT = (2^{((p-1))} \gg ((y \ll 1) \gg nScale))$, wherein y is a vertical coordinate of the sample, and $nScale$ is a scale parameter.

15 In an embodiment, the scale parameter $nScale$ is derived from a size of the block.

In an embodiment, the scale parameter $nScale$ is determined as $((\text{Log2}(nTbW) + \text{Log2}(nTbH) - 2) \gg 2)$ where $nTbW$ is a width of the block and $nTbH$ is a height of the block.

In an embodiment, the plurality of samples of the block comprises every sample of the block.

20 Further provided is a device for encoding or decoding a picture, comprising processing circuitry configured to perform any one of the above methods.

In an embodiment, the processing circuitry comprises one or more processors and a non-transitory computer-readable medium connected to the one or more processors, wherein the non-transitory computer-readable medium carries a program code which, when executed by
25 the one or more processors, causes the device to perform the method.

Further provided is a non-transitory computer-readable medium carrying a program code which, when executed by a computer device, causes the computer device to perform any one of the above methods.

CLAIMS

1. A method of intra predicting a block of a picture, comprising for a sample of the block:

5 obtaining a predicted sample value from one or more reference sample values by intra-prediction using a DC intra-prediction mode;

multiplying the predicted sample value by a sample weighting factor, resulting in a weighted predicted sample value;

adding an additional value to the weighted predicted sample value, resulting in a non-normalized predicted sample value; and

10 normalizing the non-normalized predicted sample value by an arithmetic right shift of an integer representation of the non-normalized predicted sample value, wherein

the sample weighting factor is $((2 \ll p) - wL - wT)$, wherein

p is a parameter of the sample weighting factor,

wL is a horizontal weighting factor, and

15 wT is a vertical weighting factor,

wherein the additional value is a sum of one or more summands, including a summand depending on one or more of the reference samples.

2. The method according to claim 1, comprising predicting a first block and a second block of the picture,

20 wherein an intra-prediction mode used for obtaining the predicted sample value for the first block is the DC intra-prediction mode, and an intra-prediction mode used for obtaining a predicted sample value for the second block is a PLANAR intra-prediction mode.

3. The method according to claim 1 or 2, wherein,

25 a PLANAR intra prediction mechanism is used to calculate the additional value.

4. The method according to any one of claims 1 to 3, wherein, the sample weighting factor is $(64 - wL - wT)$.

5. The method according to any one of claims 1 to 4, wherein, the summand depending on one or more reference samples is $wL \times R_{-1,y} + wT \times R_{x,-1}$, and $R_{x,-1}$ and $R_{-1,y}$ represent values of the nearest reference samples located above and to the left of the predicted sample.
- 5 6. The method according to any one of claims 1 to 5, wherein, the horizontal weighting factor wL and/or the vertical weighting factor wT is a power of two.
7. The method according to any one of claims 1 to 6, wherein,
- 10 the horizontal weighting factor is $wL = (2 \ll (p - 1)) \gg ((x \ll 1) \gg nScale)$, wherein x is a horizontal coordinate of the sample,
- the vertical weighting factor is $wT = (2 \ll (p - 1)) \gg ((y \ll 1) \gg nScale)$, wherein y is a vertical coordinate of the sample, and
- $nScale$ is a scale parameter.
- 15 8. The method according to claim 7, wherein the scale parameter $nScale$ is derived from a size of the block.
9. The method according to claim 7, wherein the scale parameter $nScale$ is determined as $((\text{Log2}(nTbW) + \text{Log2}(nTbH) - 2) \gg 2)$ where $nTbW$ is a width of the block and $nTbH$ is a height of the block.
- 20 10. The method according to any one of claims 1 to 9, wherein a normalized predicted sample value is computed from the predicted sample value, including calculating
- $$(wL \times R_{-1,y} + wT \times R_{x,-1} + (64 - wL - wT) \times P(x, y) + 32) \gg 6$$
- where
- $P(x, y)$ is the predicted sample value,
- 25 $R_{x,-1}$, $R_{-1,y}$ represent values of the nearest reference samples located above and to the left of the predicted sample,
- wL is the horizontal weighting factor, and

wT is the vertical weighting factor.

11. A method of encoding or decoding a picture, comprising:

obtaining normalized predicted sample values by performing the steps of a method according to any one of claims 1 to 10; and

adding residual values to the normalized predicted sample values resulting in reconstructed sample values.

12. A device for encoding or decoding a picture, comprising processing circuitry configured to perform the method according to any one of claims 1 to 11.

13. The device according to claim 12, wherein the processing circuitry comprises one or more processors and a non-transitory computer-readable medium connected to the one or more processors, wherein the non-transitory computer-readable medium carries a program code which, when executed by the one or more processors, causes the device to perform the method of any one of claims 1 to 12.

14. A non-transitory computer-readable medium, carrying a program code which, when executed by a computer device, causes the computer device to perform the method of any one of claims 1 to 11.

15. A computer program, comprising a program code for performing the method according to any one of claims 1 to 11.

16. A predictor device for intra predicting a block of a picture, comprising:

an obtainer configured to obtain, for a sample of the block, a predicted sample value from one or more reference sample values by intra-prediction using a DC intra-prediction mode;

a multiplier configured to multiply the predicted sample value by a sample weighting factor, resulting in a weighted predicted sample value;

an adder configured to add an additional value to the weighted predicted sample value, resulting in a non-normalized predicted sample value; and

a normalizer configured to normalize the non-normalized predicted sample value by an arithmetic right shift of an integer representation of the non-normalized predicted sample value, wherein

the sample weighting factor is $((2 \ll p) - wL - wT)$, wherein

p is a parameter of the sample weighting factor,

5 wL is a horizontal weighting factor, and

wT is a vertical weighting factor,

wherein the additional value is a sum of one or more summands, including a summand depending on one or more of the reference samples.

10 17. The predictor device according to claim 16, further configured for predicting a first block and a second block of the picture,

wherein an intra-prediction mode used for obtaining the predicted sample value for the first block is the DC intra-prediction mode, and the intra prediction mode used for obtaining a predicted sample value for the second block is a planar intra prediction mode.

15 18. A method of encoding a picture, comprising
obtaining normalized predicted sample values by performing the steps of a method according to any one of claims 1 to 10; and

20 generating residual values by deducting original sample values with the normalized predicted sample values resulting in reconstructed sample values; and

encoding the generated residual values into a bit stream.

19. A non-transitory computer-readable medium, storing bit stream encoded by the method according to claim 18.

25 20. A bit stream, encoded by the method according to claim 18.
