

## PDE9i with imidazo pyrazinone backbone

**FIELD OF THE INVENTION**

The present invention relates to cyclic guanylate monophosphate (cGMP)-specific phosphodiesterase type 9 inhibitors (hereinafter referred to as PDE9 inhibitors) of the form 7H-imidazo[1,5-a]pyrazin-8-ones for the use as a medicament. Moreover the invention relates to a pharmaceutical composition comprising 7H-imidazo[1,5-a]pyrazin-8-ones, as well as a process for preparation of the compounds.

**BACKGROUND OF THE INVENTION**

10 The phosphodiesterases (PDEs) are a superfamily of enzymes that metabolically inactivate the ubiquitous intracellular messengers cAMP and cGMP. This function involves the PDEs in a broad range of important cellular functions, such as immune response, memory, and vision. The human genome encodes for 21 PDEs that are categorized into 11 families (Mehats C, Andersen CB, Filopanti M, Jin SL, Conti M. "Cyclic nucleotide phosphodiesterases and their  
15 role in endocrine cell signaling." Trends Endocrinol Metab. 2002;13:29–35). These enzymes share a conserved catalytic domain of approximately 300 amino acids that is located in the C-terminal region of the protein. The N-terminal regions, which vary among different PDEs, serve regulatory functions including autoinhibition of the catalytic domains or control of sub-cellular localization (Mehats 2002). The PDEs have different substrate preferences: Cyclic  
20 guanylate monophosphate (cGMP)-specific phosphodiesterase type 9 (PDE9) is a member of the PDE enzyme family that selectively hydrolyses cGMP over cAMP (D A Fisher et al., J. Biol. Chemistry, vol. 273, No. 25, 15559-15564 (1998)). The different substrate preferences, combined with different expression profiles, cellular compartmentalization, and regulation, allow the PDEs to play a very versatile role in cell signal transduction (Breer H, Boekhoff I, Tareilus E. "Rapid kinetics of second messenger formation in olfactory transduction." Nature.  
25 1990;345:65–68).

PDE9 inhibitors have been reported as useful to treat cardiovascular disorders (WO 03/037899), and insulin resistance syndrome, hypertension, and/or type 2 diabetes (WO 03/037432) as well as for treatment of obesity related conditions (WO/2005/041972).

30 Wunder F. et al (Mol. Pharmacol. 2005 Dec; 68(6):1775-81, 2005) report the in vitro characterization of 1-(2-chlorophenyl)-6-[(2R)-3,3,3-trifluoro-2-methylpropyl]-1,5-dihydro-4H-pyrazolo[3,4-d]pyrimidine-4-one, a selective inhibitor of phosphodiesterase 9 (PDE9), which is

under development for the treatment of Alzheimer's disease. This compound is reported to inhibit human (IC<sub>50</sub> = 55 nM) and murine (IC<sub>50</sub> = 100 nM) PDE9 activity in vitro.

Over the years convincing experimental evidence has accumulated supporting the cognition-enhancing properties of several classes of PDE-inhibitors (Blokland et al., 2006: "Improving memory; a role for phosphodiesterases", Current Pharmacological Design 12, 2511-2523).

In a later study van der Staay et al. (F. Josef van der Staay, Neuropharmacology Volume 55, Issue 5, October 2008, pages 908-918) concludes that the PDE9 inhibitor 1-(2-chlorophenyl)-6-[(2R)-3,3,3-trifluoro-2-methylpropyl]-1,5-dihydro-4H-pyrazolo[3,4-d]pyrimidine-4-one may act as a putative cognition enhancer.

Alzheimers disease is the most common form of dementia, it is incurable, degenerative, and terminal. The typical symptoms are cognitive difficulties, difficulties with executive functioning (such as planning, organization, mental flexibility and task coordination) as well as with perception (agnosia) and execution of movements (apraxia).

Because AD cannot be cured and is degenerative, palliative treatment of patients is essential.

## SUMMARY OF THE INVENTION

The present invention discloses novel PDE9 inhibitors for the use as a medicament, such as in the treatment of patients suffering from cognitive impairments, in particular cognitive impairments that relate to neurodegenerative diseases such as cortical dementia (e.g. Alzheimer's disease) or subcortical dementia, e.g. AIDS related dementia.

The PDE9 inhibitors of the present invention have the structure I (i.e. a 7H-imidazo[1,5-a]pyrazin-8-one backbone):

(I)

wherein R2 is cyclized with either R1 or R3.

The invention relates to methods of improving conditions involving PDE9, such as cognition, in particular the invention relates to a method of treating diseases involving cognitive difficul-

ties, difficulties with executive functioning (such as planning, organization, mental flexibility and task coordination) as well as with perception (agnosia). The methods of improving conditions involving PDE9 and/or treating diseases involving PDE9 comprises the administration of a compound of the present invention or a pharmaceutically acceptable salt, solvate or prodrug thereof to a patient in need thereof. The compound of the present invention or a pharmaceutically acceptable salt, solvate or prodrug thereof may be in the form of a pharmaceutical composition.

In a further aspect the invention relates to an improved pharmaceutical composition comprising a compound of the present invention particularly useful for the treatment of cognitive difficulties, difficulties with executive functioning (such as planning, organization, mental flexibility and task coordination) as well as with perception (agnosia), in particular when associated neurodegenerative diseases, such as cortical or subcortical dementias, e.g. Alzheimer's disease (AD).

#### **DETAILED DESCRIPTION OF THE INVENTION**

Cognitive impairment includes a decline in cognitive functions or cognitive domains, such as, e.g., difficulties with attention, learning, memory and executive function (relevant reactions to external stimuli). Cognitive impairment also may include: deficits in attention, disorganized thinking, slow thinking, difficulty in understanding, poor concentration, impairment of problem solving, poor memory, difficulty in expressing thoughts and/or integrating thoughts, feelings and behaviour, and/or extinction of irrelevant thoughts, and difficulty in attention and vigilance, verbal learning and memory, visual learning and memory, speed of processing, social cognition, reasoning and problem solving, e.g., executive functioning. There are presently no effective drugs for the treatment of cognitive disorders on the market and there is a great need and demand for drugs effective in the treatment of such disorders.

Without being limited to any specific theory it is believed that the mode of action of PDE9 inhibitors can be understood in the light of the following neurological processes: guanylyl cyclase (alt. guanylate cyclase) converts guanosine triphosphate (GTP) to cyclic guanosine monophosphate (cGMP), which in turn activates cGMP-dependent protein kinase G (PKG). PKG is known to lower the threshold for the induction of long-term potentiation (LTP), i.e. the long-lasting improvement in communication between neurons (Zhou et al., 1994: "Role of guanylyl cyclase and cGMP-dependent protein kinase in long-term potentiation", Nature 368, 635-639). The communication between neurons takes place via the chemical synapses (synaptic transmission) and because memories are believed to be stored within these synapses, LTP is considered one of major cellular mechanisms that underlies cognition (Boron, W. F.,

2005: Medical Physiology: A Cellular and Molecular Approach. Elsevier/Saunders, ISBN 1-4160-2328-3 and Cooke et al., 2006 "Plasticity in the human central nervous system". Brain 129, 1659-1673). As a result high levels of cGMP will eventually lead to improvement of cognition via the activation of PKG. The level of cGMP can be increased by inhibition of PDE9, which – as mentioned above – has the highest affinity for cGMP of any of the PDEs. Accordingly, PDE9 inhibitors will improve synaptic transmission and thereby enhance cognitive performance as evidenced by the results presented in the experimental section.

The invention will be illustrated in the following non-limiting examples.

It will be appreciated that the route will depend on the general condition and age of the subject to be treated, the nature of the condition to be treated and the active ingredient.
- 30

Pharmaceutical compositions for oral administration include solid dosage forms such as capsules, tablets, dragees, pills, lozenges, powders and granules. Where appropriate, the compositions may be prepared with coatings such as enteric coatings or they may be formulated so as to provide controlled release of the active ingredient such as sustained or prolonged release according to methods well known in the art. Liquid dosage forms for oral administration include solutions, emulsions, suspensions, syrups and elixirs.

Pharmaceutical compositions for parenteral administration include sterile aqueous and nonaqueous injectable solutions, dispersions, suspensions or emulsions as well as sterile powders to be reconstituted in sterile injectable solutions or dispersions prior to use. Other suitable administration forms include, but are not limited to, suppositories, sprays, ointments, creams, gels, inhalants, dermal patches and implants.

Typical oral dosages range from about 0.001 to about 100 mg/kg body weight per day. Typical oral dosages also range from about 0.01 to about 50 mg/kg body weight per day. Typical oral dosages further range from about 0.05 to about 10 mg/kg body weight per day. Oral dosages are usually administered in one or more dosages, typically, one to three dosages per day. The exact dosage will depend upon the frequency and mode of administration, the sex, age, weight and general condition of the subject treated, the nature and severity of the condition treated and any concomitant diseases to be treated and other factors evident to those skilled in the art.

The formulations may also be presented in a unit dosage form by methods known to those skilled in the art. The present invention also provides a process for making a pharmaceutical composition comprising admixing a therapeutically effective amount of a compound of formula (I) and at least one pharmaceutically acceptable carrier or diluent. In an embodiment, of the present invention, the compound utilized in the aforementioned process is one of the specific compounds disclosed in the Experimental Section herein.

The compounds of this invention are generally utilized as the free substance or as a pharmaceutically acceptable salt thereof. One example is an acid addition salt of a compound having the utility of a free base. When a compound of formula (I) contains a free base such salts are

prepared in a conventional manner by treating a solution or suspension of a free base of formula (I) with a molar equivalent of a pharmaceutically acceptable acid. Representative examples of suitable organic and inorganic acids are described above.

For parenteral administration, solutions of the compounds of formula (I) in sterile aqueous solution, aqueous propylene glycol, aqueous vitamin E or sesame or peanut oil may be employed. Such aqueous solutions should be suitably buffered if necessary and the liquid diluent first rendered isotonic with sufficient saline or glucose. The aqueous solutions are particularly suitable for intravenous, intramuscular, subcutaneous and intraperitoneal administration. The compounds of formula (I) may be readily incorporated into known sterile aqueous media using standard techniques known to those skilled in the art.

Suitable pharmaceutical carriers include inert solid diluents or fillers, sterile aqueous solutions and various organic solvents. Examples of solid carriers include lactose, terra alba, sucrose, cyclodextrin, talc, gelatin, agar, pectin, acacia, magnesium stearate, stearic acid and lower alkyl ethers of cellulose. Examples of liquid carriers include, but are not limited to, syrup, peanut oil, olive oil, phospholipids, fatty acids, fatty acid amines, polyoxyethylene and water. Similarly, the carrier or diluent may include any sustained release material known in the art, such as glyceryl monostearate or glyceryl distearate, alone or mixed with a wax. The pharmaceutical compositions formed by combining the compounds of formula (I) and a pharmaceutically acceptable carrier are then readily administered in a variety of dosage forms suitable for the disclosed routes of administration. The formulations may conveniently be presented in unit dosage form by methods known in the art of pharmacy.

Formulations of the present invention suitable for oral administration may be presented as discrete units such as capsules or tablets, each containing a predetermined amount of the active ingredient, and optionally a suitable excipient. Furthermore, the orally available formulations may be in the form of a powder or granules, a solution or suspension in an aqueous or non-aqueous liquid, or an oil-in-water or water-in-oil liquid emulsion.

If a solid carrier is used for oral administration, the preparation may be tableted, placed in a hard gelatin capsule in powder or pellet form or it may be in the form of a troche or lozenge. The amount of solid carrier will vary widely but will range from about 25 mg to about 1 g per dosage unit. If a liquid carrier is used, the preparation may be in the form of a syrup, emulsion, soft gelatin capsule or sterile injectable liquid such as an aqueous or non-aqueous liquid suspension or solution.

The pharmaceutical compositions of the invention may be prepared by conventional methods in the art. For example, tablets may be prepared by mixing the active ingredient with ordinary adjuvants and/or diluents and subsequently compressing the mixture in a conventional tableting machine prepare tablets. Examples of adjuvants or diluents comprise: corn starch, potato starch, talcum, magnesium stearate, gelatin, lactose, gums, and the like. Any other adjuvants or additives usually used for such purposes such as colorings, flavorings, preservatives etc. may be used provided that they are compatible with the active ingredients.

### Diseases

In a particular embodiment the PDE9 inhibitors of the present invention may be used in the treatment of cognition deficiencies related to neurodegenerative disorders, such dementia, such as cortical dementia or subcortical dementia.

Cortical dementias arise from a disorder affecting the cerebral cortex, the outer layers of the brain that play a critical role in cognitive processes such as memory and language. Particularly considered cortical dementias are Alzheimer's disease; vascular dementia (also known as multi-infarct dementia), including Binswanger's disease; Dementia with Lewy bodies (DLB); Alcohol-Induced Persisting Dementia, including Korsakoff's syndrome and Wernicke's encephalopathy; frontotemporal lobar degeneration (FTLD), including: Pick's disease, frontotemporal dementia (or frontal variant FTLD), semantic dementia (or temporal variant FTLD), and progressive non-fluent aphasia; Creutzfeldt-Jakob disease; dementia pugilistica; Moya-moya disease; and posterior cortical atrophy (an Alzheimer's disease variant).

Subcortical dementias result from dysfunction in the parts of the brain that are beneath the cortex. Usually, the memory loss and language difficulties that are characteristic of cortical dementias are not present. Rather, people with subcortical dementias, such as Huntington's disease, Parkinson's Disease, and AIDS dementia complex, tend to show changes in their personality and attention span, and their thinking slows down. Particularly considered subcortical dementias are dementia due to Huntington's disease, dementia due to hypothyroidism, dementia due to Parkinson's disease, dementia due to Vitamin B1 deficiency, dementia due to Vitamin B12 deficiency, dementia due to folate deficiency, dementia due to syphilis, dementia due to subdural hematoma, dementia due to hypercalcaemia, dementia due to hypoglycaemia, AIDS dementia complex, pseudodementia (a major depressive episode with prominent cognitive symptoms), substance-induced persisting dementia, dementia due to multiple etiologies, dementia due to other general medical conditions (i.e. end stage renal failure, cardiovascular disease etc.), dementia not otherwise specified (used in cases where no specific criteria is met).

## IN VITRO TESTING

### PDE9 inhibition assay

A PDE9 assay may for example, be performed as follows: The assay is performed in 60 µL samples containing a fixed amount of the relevant PDE enzyme (sufficient to convert 20-25% of the cyclic nucleotide substrate), a buffer (50 mM HEPES 7.6; 10mM MgCl<sub>2</sub>; 0.02% Tween20), 0.1mg/ml BSA, 225 pCi of <sup>3</sup>H-labelled cyclic nucleotide substrate, tritium labeled cAMP to a final concentration of 5 nM and varying amounts of inhibitors. Reactions are initiated by addition of the cyclic nucleotide substrate, and reactions are allowed to proceed for

one hr at room temperature before being terminated through mixing with 15 uL 8 mg/mL yttrium silicate SPA beads (Amersham). The beads are allowed to settle for one hr in the dark before the plates are counted in a Wallac 1450 Microbeta counter. The measured signal can be converted to activity relative to an uninhibited control (100 %) and IC<sub>50</sub> values can be calculated using the Xlfit extension to EXCEL.

In the context of the present invention the assay was performed in 60 uL assay buffer (50 mM HEPES pH 7.6; 10mM MgCl<sub>2</sub>; 0.02% Tween20) containing enough PDE9 to convert 20-25% of 10 nM <sup>3</sup>H-cAMP and varying amounts of inhibitors. Following a 1 hour incubation the reactions were terminated by addition of 15 uL 8 mg/mL yttrium silicate SPA beads (Amersham). The beads were allowed to settle for one hr in the dark before the plates were counted in a Wallac 1450 Microbeta counter. IC<sub>50</sub> values were calculated by non linear regression using XLfit (IDBS).

Results of the experiments showed that the tested compounds of the invention inhibit the PDE9 enzyme with IC<sub>50</sub> values below 250 nM.
